Open-Minded

Mixed Least Squares Finite Element Methods for Hyperelastic Materials

Supported by the German Research Foundation (DFG) under grant STA402/11-1 and SCHR570/14-1

Motivation:

The finite element method is an important tool for the simulation of elasticity problems in solid mechanics. It is well known that the linear elastic theory does not cover arising real life problems. Physically more realistic models lead to nonlinear partial differential equations. The least squares finite element method is until now only rarely investigated for nonlinear deformation processes despite its advantages, e.g. providing a candidate for a - posteriori error estimation and not being restricted to certain finite element spaces (inf-sup condition).

Problem description:

Possible forces are volume forces, acting on the whole body Ω , and surface forces, acting on the Neumann boundary Γ_N . Applied forces on an unloaded body lead to a deformation φ and related stresses.

The balance of momentum and the (nonlinear) constitutive equation are basic ingredients for modelling deformation processes mathematically.

We use a homogeneous isotropic hyperelastic material of Neo-Hookean type with stored energy function

$$\psi(\mathbf{C}) = \frac{\mu}{2}\operatorname{tr}(\mathbf{C}) + \frac{\lambda}{4}\det\mathbf{C} - \left(\frac{\lambda}{2} + \mu\right)\ln\sqrt{\det\mathbf{C}}$$

and Lamé constants λ,μ for minimizing the nonlinear least squares functional

$$\mathcal{F}(\mathbf{P}, \mathbf{u}) = \omega_1^2 \| \mathsf{div} \ \mathbf{P} + \mathbf{f} \|^2 + \omega_2^2 \| \mathcal{A}(\mathbf{PF}(\mathbf{u})^T) - \mathbf{B}(\mathbf{u}) \|^2$$

in appropriate function spaces. Here $\mathbf{P}=\partial_{\mathbf{F}}\psi(\mathbf{C})$ denotes the first Piola - Kirchhoff stress tensor, \mathbf{u} the pointwise displacement, ω_1 and ω_2 suitable weighting parameters and \mathbf{f} the acting volume force.

Algorithmic implementation:

- + Gauss-Newton method for minimization of $\mathcal{F}(\mathbf{P},\mathbf{u})$
- Raviart-Thomas elements \mathcal{RT}_1 for each row of \mathbf{P} and continuous piecewise quadratic elements for each component of \mathbf{u}
- backtracking line search as damping strategy

Numerical results for the incompressible case: 1. Detection of critical load values:

Given: $\Omega = (-1, 1) \times (-1, 1)$, $\mathbf{f} = (0, \gamma)^T$ with $\gamma \in \mathbb{R}$, $\mathbf{u} \cdot \mathbf{n} = 0$ and $(\mathbf{P} \cdot \mathbf{n}) \cdot \mathbf{t} = 0$ (left, bottom, right boundary), $\mathbf{P} \cdot \mathbf{n} = \mathbf{0}$ (top boundary)

2. Adaptivity for a plane strain model (Cook's membrane in 2d):

Given: $\mathbf{f} = \mathbf{0}$, $\mathbf{u} = \mathbf{0}$ (left boundary), $\mathbf{P} \cdot \mathbf{n} = \mathbf{0}$ (top/bottom boundary) and $\mathbf{P} \cdot \mathbf{n} = (0, \gamma)^T$ (right boundary) with load parameter $\gamma = 0.1$

nt	$\mathcal{F}(\mathbf{P}_h,\mathbf{u}_h)$	(order)	$\mathbf{u}_2(48, 60)$
131	$1.27 \cdot 10^{-1}$		8.2461
192	$5.89 \cdot 10^{-2}$	(2.02)	8.4005
271	$2.85 \cdot 10^{-2}$	(2.11)	8.4638
400	$1.38 \cdot 10^{-2}$	(1.87)	8.4932

1267	$1.24 \cdot 10^{-3}$	(2.25)	8.5168
1893	$5.09 \cdot 10^{-4}$	(2.22)	8.5178
	nt 131 192 271 400 593 868 1267 1893	$\begin{array}{ c c c c c c } & nt & \mathcal{F}(\mathbf{P}_h,\mathbf{u}_h) \\ \hline 131 & 1.27\cdot 10^{-1} \\ \hline 192 & 5.89\cdot 10^{-2} \\ \hline 271 & 2.85\cdot 10^{-2} \\ \hline 400 & 1.38\cdot 10^{-2} \\ \hline 593 & 6.43\cdot 10^{-3} \\ \hline 868 & 2.90\cdot 10^{-3} \\ \hline 1267 & 1.24\cdot 10^{-3} \\ \hline 1893 & 5.09\cdot 10^{-4} \\ \hline \end{array}$	$\begin{array}{ c c c c c c c } \hline \text{nt} & \mathcal{F}(\mathbf{P}_h,\mathbf{u}_h) & (\text{order}) \\ \hline 131 & 1.27\cdot10^{-1} & & \\ \hline 192 & 5.89\cdot10^{-2} & (2.02) \\ \hline 271 & 2.85\cdot10^{-2} & (2.11) \\ \hline 400 & 1.38\cdot10^{-2} & (1.87) \\ \hline 593 & 6.43\cdot10^{-3} & (1.94) \\ \hline 868 & 2.90\cdot10^{-3} & (2.09) \\ \hline 1267 & 1.24\cdot10^{-3} & (2.22) \\ \hline 1893 & 5.09\cdot10^{-4} & (2.22) \\ \hline \end{array}$

3. Cook's membrane in 3d:

Given: $\mathbf{f} = \mathbf{0}$, $\mathbf{u} = \mathbf{0}$ (left boundary), $\mathbf{P} \cdot \mathbf{n} = (0, \gamma, 0)^T$ (right boundary) with load parameter $\gamma = 0.1$, $\mathbf{P} \cdot \mathbf{n} = \mathbf{0}$ (other four boundaries)

Conclusion:

Our least squares finite element approach has an essential advantage compared to other methods, namely the full stress tensor is approximated next to the displacement. Our approach is suitable for the incompressible limit and provides good results for 2d and 3d simulations. The least squares functional as error estimator tends to identify the regions of interest in our considered numerical experiments.
