Prof. Dr. Tim Salditt, Institut für
R ntgenphysik, Universität G ttingen

X rays can deeply penetrate matter and thus provide information about the functional (interior) architecture of complex samples, from biological tissues and cells to nanoscale composite materials. Until recently, however, this potential of hard xrays in view of penetration, spatial resolution, contrast, and compatibility with environmental conditions was significantly limited by the lack in suitable in xray optics. With the advent of highly brilliant radiation, and the development of lens less diffractive imaging and coherent focusing, the situation has changed. We now have nano focused coherent xray synchrotron beams at hand to probe nanoscale structures both in scanning and in full field imaging and tomography. We explain how the central challenge of inverting the coherent diffraction pattern can be mastered by different reconstruction algorithms in the optical far and nearfield. In particular, we present full field pro ection imaging at high magnification, recorded by illumination with advanced xray waveguide optics 1 , and show how imaging and diffraction can be combined to investigate biomolecular structures within biological cells. We present different examples of biophysical and biomedical applications , , including dvirtual histology of human brain tissue 4 .
