A fourth order gauge-invariant gradient plasticity model for polycrystals based on Kröner’s incompatibility tensor

François Ebobisse¹ and Patrizio Neff²

June 29, 2017

Dedicated to Elias C. Aifantis, pioneer of gradient plasticity

Abstract

In this paper we derive a novel fourth order gauge-invariant phenomenological model of infinitesimal rate-independent gradient plasticity with isotropic hardening and Kröner’s incompatibility tensor \( \text{inc}(\varepsilon_p) := \text{Curl}[(\text{Curl} \varepsilon_p)^T] \), where \( \varepsilon_p \) is the symmetric plastic strain tensor. Here, gauge-invariance denotes invariance under diffeomorphic reparametrizations of the reference configuration, suitably adapted to the geometrically linear setting. The model features a defect energy contribution which is quadratic in the tensor \( \text{inc}(\varepsilon_p) \) and it contains isotropic hardening based on the rate of the plastic strain tensor \( \dot{\varepsilon}_p \). We motivate the new model by introducing a novel rotational invariance requirement in gradient plasticity, which we call micro-randomness, suitable for the description of polycrystalline aggregates on a mesoscopic scale and not coinciding with classical isotropy requirements. This new condition effectively reduces the increments of the non-symmetric plastic distortion \( \dot{p} \) to their symmetric counterpart \( \dot{\varepsilon}_p = \text{sym} \dot{p} \). In the polycrystalline case, this condition is a statement about insensitivity to arbitrary superposed grain rotations. We formulate a mathematical existence result for a suitably regularized non-gauge-invariant model. The regularized model is rather invariant under reparametrizations of the reference configuration including infinitesimal conformal mappings.

Key words: plasticity, gradient plasticity, geometrically necessary dislocations, incompatible distortions, rate-independent models, kinematic hardening, backstress, Bauschinger effects, variational inequality, defect energy, incompatibility tensor, Riemann-Christoffel tensor, dislocation density, gauge theory of dislocations, Lanczos scalar, infinitesimal conformal mappings, isotropy, indeterminacy of multiplicative split.

1. Introduction

In recent years there has been a growing attention in extending continuum plasticity theories towards the incorporation of the experimentally observed size-effects in small scales (see e.g. [45, 47, 117, 127]). This extension is mainly done via the introduction of certain gradient terms, making the plastic evolution in some sense nonlocal. Perhaps the earliest such phenomenological model is due to Aifantis et al. [3, 4, 91, 134], who directly incorporated the Laplacian $\Delta \gamma_p$ in the flow stress, where $\gamma_p := \int_0^t \| \dot{\varepsilon}_p \| \, ds$ is a measure of accumulated equivalent plastic strain\(^1\) (see Table 1 below for a summary). Other variants of the Aifantis’ model also based on the accumulated plastic strain were proposed later through the principle of virtual power by Fleck and Hutchinson [46], Gudmundson [51] and generalized by Gurtin and Anand [57].

While there are numerous proposals of such gradient enhanced phenomenological models, either based on the multiplicative decomposition

\[ F = F_e \cdot F_p \]  
(1.1)

(see e.g. [2, 26, 56, 99]), or based on the geometrically linearized corresponding additive decomposition

\[ \varepsilon = \varepsilon_e + \varepsilon_p \]  
(1.2)

\(^1\)Cf. e.g. Hill [62, p.30].
A fourth order gradient plasticity model based on Kröner’s incompatibility tensor

\[ \text{sym} \nabla u = \varepsilon = \varepsilon_e + \varepsilon_p, \quad \varepsilon_p \in \text{Sym}(3) \]
\[ \sigma_y = \sigma_0 + \mu k_2 \gamma_p - \mu L_c^2 \Delta \gamma_y, \quad \sigma_y \text{ is the current yield stress} \]
\[ L_c > 0 \text{ material length scale} \]
\[ \sigma_0 > 0 \text{ the initial yield stress} \]
\[ k_2 \text{ can be taken negative for local softening behaviour} \]
\[ \gamma_p := \int_0^t \| \dot{\varepsilon}_p \| \, ds \text{ the accumulated equivalent plastic strain} . \]

Table 1: A summary of the model by Aifantis [3, 4, 91] based on the accumulated equivalent plastic strain \( \gamma_p \). Depending on the sign of \( \Delta \gamma_p \), the model describes process-dependent hardening (\( \Delta \gamma_p < 0 \)) or softening (\( \Delta \gamma_p > 0 \)) due to nonlocal effects.

(see e.g. [3, 4, 91, 46, 51, 55, 57, 59, 83, 84, 91, 129]), no general consensus has been reached as to which variables describing the plastic evolution should be employed and how they should be combined with their partial derivatives in space. For example, a dependence of the plastic flow rule directly via the infinitesimal plastic strain variable \( \varepsilon_p \) is sometimes excluded, since the backstress variable \( \varepsilon_p \) is not gauge-invariant.\(^2\)

However, if \( \varepsilon_p \) is not allowed to appear itself in the equations, then linear kinematic hardening \( \text{á la Prager} \) is excluded from the onset, while the modelling of classical linear isotropic hardening remains possible since it is based on \( \| \dot{\varepsilon}_p \| \), which is invariant under reparametrization of the reference configuration (gauge-invariance), see subsection 3.1 in this paper.

With the use of an evolution equation for the symmetric plastic strain tensor \( \varepsilon_p \) being traditional, there are also approaches which focus directly on the plastic distortion \( p \) (which is a non-symmetric variable), thus allowing for the so-called plastic spin\(^3\) (see [58, p.493 and eqs. (91.7) and (91.10)] and also [30, 67, 81, 15, 119, 17]). The connection between the two approaches is simple: we can always identify \( \varepsilon_p := \text{sym} \ p \). As it will turn out subsequently, the introduction of the plastic distortion \( p \) will make our modelling framework much more transparent: on the one hand, the passage from the multiplicative decomposition to the additive decomposition via formal geometric linearization is easier and the discussion of invariance conditions becomes clearer, even if in the end we obtain a model for the plastic strain tensor \( \varepsilon_p = \text{sym} \ p \) only.

Our aim with this paper is to present a rational modelling environment for gradient plasticity with respect to the small strain framework and the additive decomposition which incorporates certain insights learned from the multiplicative decomposition.

Let us therefore collect what the model should be able to do. It should

- incorporate energetic hardening (due to Geometrically Necessary Dislocations, GNDs) related to the energetic length scale \( L_c \);

\(^2\)Aifantis writes in [4, p. 218]: “"... In conformity with established results - that the plastic strain rate \( \dot{\varepsilon}_p \) is a state variable, rather than the strain \( \varepsilon_p \) itself.""

\(^3\)The plastic spin in the finite deformation flow theory of plasticity is defined as the skew-symmetric part of the so-called plastic distortion rate i.e., \( W_p := \text{skew}(\dot{F}_p F_p^{-1}) \), while its counter-part in the small strain theory is simply \( \text{skew}(\dot{p}) \), where \( p \) is the non-symmetric infinitesimal plastic distortion.
- incorporate nonlocal hardening (backstress and Bauschinger effects);
- satisfy appropriate invariance conditions (objectivity, referential isotropy, independence of reference configuration, gauge-invariance, elastic isotropy, elastic frame-indifference, etc.);
- allow in principle for plastic spin (Bardella [15, 16], Gurtin [54], Neff et al. [99], Ebobisse et al. [36, 40, 39]);
- satisfy an extended positive dissipation principle and be therefore thermodynamically admissible;
- be able to be cast in a convex analytical framework;
- support a well-posedness result in both the rate-independent and the rate-dependent cases;
- have physical meaningful and transparent boundary conditions for the plastic variables.

In this paper, we will propose such a model, which, in the end, has a certain resemblance with the early model proposed by Menzel and Steinmann [84] and we will show its well-posedness in the rate-independent case with a suitable regularization. Our derivation of the model based on invariance principles is, to our knowledge, entirely new. The model is derived through a process of linearization of some state variables in the finite strain case. The derivation of a linear model from a finite strain one is not new in the context of elasto-plasticity. For instance, Mielke and Stefanelli [88] used Γ-convergence to derive rigorously a model of linearized plasticity as limit of some finite strain plasticity model.

The mathematical well-posedness of our model seems to be interesting in its own right. Once more, the convex analytical framework, based on incorporating the postulate of maximum plastic dissipation, put forward initially by Moreau [90] and used later by many authors (e.g. [60, 33, 122, 99, 35, 36, 37, 38, 40, 39]), proves to be ideally suited. For that purpose, our ”additive” model also admits a finite strain parent model by Krishnan and Steigmann [69], who did not consider, however, the incorporation of (nonlocal) kinematic hardening.

Decisive for our new strain gradient plasticity model is the introduction of Kröner’s incompatibility tensor $\text{inc}(\text{sym } \varepsilon_p) := \text{Curl}((\text{Curl sym } \varepsilon_p)^T)$ as an inhomogeneity measure acting on the symmetric plastic strain $\varepsilon_p = \text{sym } p$. This incompatibility tensor is given by

$$\text{inc}(\text{sym } p) := \text{Curl}((\text{Curl sym } p)^T)$$  \hspace{1cm} (1.3)

and it coincides to first order with the Riemann-Christoffel curvature tensor $\mathcal{R}$ in the metric characterized by the finite plastic strain tensor $C_p := F_p^T F_p$ (De Wit [32]). In fact, considering the non-symmetric plastic distortion $F_p$ in the multiplicative decomposition (1.1) and writing $F_p = \mathbb{1} + p$, the connection is

$$\mathcal{R}(F_p^T F_p) = \mathcal{R}((\mathbb{1} + p)^T (\mathbb{1} + p)) = \mathcal{R}(\mathbb{1} + 2 \text{sym } p + p^T p) = 2 \text{inc}(\text{sym } p) + \text{h.o.t.},$$  \hspace{1cm} (1.4)

---

The postulate of maximum plastic dissipation (PMPD), which was derived independently in classical infinitesimal theory of plasticity from the so-called Drucker’s postulate by von Mises [89], Taylor [130], Hill [63] Mandel [79] (and later as a consequence of Il’ushin’s postulate of plasticity in strain space) has the form $\langle \sigma - \sigma^*, \dot{\varepsilon}_p \rangle \geq 0$, where $\sigma$ is the actual stress tensor, $\dot{\varepsilon}_p$ is the plastic strain-rate tensor and $\sigma^*$ is any admissible stress tensor. The PMPD is equivalent to the associated flow rule in the dual formulation in the local theory of plasticity. The maximal dissipation (associated flow rule) simplifies the modelling framework and facilitates the mathematical treatment.
where\(^5\)

\[
\mathcal{R}_{ijkl}(C_p) := \frac{\partial \Gamma_{ji}^l}{\partial x_k} - \frac{\partial \Gamma_{jk}^i}{\partial x_l} + \Gamma_{mj}^i \Gamma_{mk}^l - \Gamma_{mj}^l \Gamma_{mk}^i,
\]

(1.5)

with

\[
\Gamma_{lj}^i := \frac{1}{2} g_{kl} \left[ \frac{\partial g_{ki}}{\partial x_j} + \frac{\partial g_{jk}}{\partial x_i} - \frac{\partial g_{ij}}{\partial x_k} \right],
\]

being the Christoffel symbols of the second kind in the metric \(C_p = (g_{ij})\) whose inverse is \(C_p^{-1} = (g^{ij})\).

Assume that we change the reference configuration by a smooth invertible map

\[
\psi : \xi \mapsto x(\xi),
\]

(1.6)

then the plastic distortion \(F_p\) in the multiplicative decomposition (1.1) should transform according to

\[
F_p(x) \rightarrow F_p(x(\xi)) \frac{\partial x(\xi)}{\partial \xi} = \tilde{F}_p(\xi) \nabla_\xi \psi(\xi).
\]

(1.7)

Based on the Riemann-Christoffel curvature tensor \(\mathcal{R}\) in (1.5), we may form a "true scalar" quantity, namely the so-called \textit{Lanczos scalar}

\[
\sum_{ijkl} \mathcal{R}_{ijkl} \cdot \mathcal{R}_{ijkl} \simeq \|\mathcal{R}\|^2,
\]

(1.8)

which is \textit{form-invariant} under a change of the reference configuration in the sense that

\[
\left\| \mathcal{R}_x(F_p(x)^T F_p(x)) \right\|^2 = \left\| \mathcal{R}_\xi((\tilde{F}_p(\xi) \nabla_\xi \psi(\xi))^T (\tilde{F}_p(\xi) \nabla_\xi \psi(\xi))) \right\|^2,
\]

(1.9)

(see Lanczos [73, eq. (2.3)]) where \(\mathcal{R}_x\) and \(\mathcal{R}_\xi\) denote the Riemann-Christoffel curvature tensor expressed in coordinates \(x\) and \(\xi\), respectively. Moreover, if we consider the transformation

\[
F_p(x) \rightarrow \tilde{F}_p := Q(x) F_p(x), \quad \text{with arbitrary } Q(x) \in \text{O}(3),
\]

(1.10)

then we have the direct invariance condition for the Riemann-Christoffel curvature tensor

\[
\mathcal{R}_x(F_p(x)^T F_p(x)) = \mathcal{R}_x(F_p(x)^T Q(x)^T Q(x) F_p(x)) = \mathcal{R}_x((Q(x) F_p(x))^T Q(x) F_p(x)) = \mathcal{R}_x(\tilde{F}_p(x)^T \tilde{F}_p(x)).
\]

(1.11)

The form-invariance property (1.9) is inherited in its geometric linearization, now by the inc-operator, in the form of a direct invariance condition for the complete operator (and not just the “Lanczos”-type scalar \(\|\text{inc}_x \text{ sym } p\|^2\)):

\[
\text{inc}_x(\text{sym } p(x)) = \text{inc}_x(\text{sym } (p(x) + \nabla_x \vartheta(x)) \quad \forall \vartheta(x) \in C^1(\mathbb{R}^3, \mathbb{R}^3),
\]

(1.12)

where we have identified \(\psi(x) = x + \vartheta(x)\). In fact, from the identity (see [48, Proposition 2.1])

\[
\nabla axl(\text{skew } \nabla \vartheta) = \frac{1}{2} \nabla \text{curl } \vartheta = (\text{Curl } \text{sym } \nabla \vartheta)^T,
\]

(1.13)

\(^5\)Note that \(\mathcal{R}_{ijkl}^i\) is both geometrically and physically nonlinear.
taking the Curl on both sides, we get

\[ 0 = \text{Curl} \left( \frac{1}{2} \nabla \text{curl} \vartheta \right) = \text{Curl} \left[ (\text{Curl} \text{ sym} \nabla \vartheta)^T \right] = \text{inc} (\text{sym} \nabla \vartheta), \]

which shows (1.12). Of course (1.12) implies that

\[ \| \text{inc}_x (\text{sym} p(x)) \|^2 = \| \text{inc}_x (\text{sym} (p(x) + \nabla_x \vartheta(x))) \|^2 \quad \forall \vartheta(x) \in C^1(\mathbb{R}^3, \mathbb{R}^3), \]

mirroring property (1.9) for the Lanczos-type scalar.

In addition, the direct invariance condition (1.11) for \( R \) under rotation fields \( Q(x) \in SO(3) \) translates to an invariance condition on the inc-operator as well. We write

\[ p(x) \rightarrow A(x) + p(x) \quad \forall A(x) \in \mathfrak{so}(3) \]

and we have the invariance condition

\[ \text{inc}_x (\text{sym} p(x)) = \text{inc}_x (\text{sym} (A(x) + p(x))) \quad \forall A(x) \in \mathfrak{so}(3). \]

For both tensors \( R \) and inc we note the Saint-Venant compatibility condition and its linearization:

\[ \psi(x) = x + \vartheta(x) \quad \text{and} \quad C_p = F_p^T F_p = \mathbf{1} + \varepsilon_p + \text{h.o.t} \]

\[ C_p = F_p^T F_p \in \text{Sym}^+(3) \text{ symmetric positive definite} \]

\[ R(C_p) = 0 \iff C_p = \nabla \psi^T \nabla \psi \]

\[ \text{See e.g. Ciarlet-Laurent [29, Theorem 1.1]} \]

\[ \approx \text{inc}(\text{sym} p) = 0 \iff \text{sym} p = \text{sym} \nabla \vartheta \]

in simply connected domains (see [82, 28, 29, 78]). For more properties of the inc-operator, we refer the reader to [133, 10, 78].

With these preliminaries, both tensors \( R \) and inc qualify as incompatibility measures on positive definite symmetric plastic strains \( C_p = F_p^T F_p \) in the geometrically nonlinear and on symmetric plastic strains \( \varepsilon_p = \text{sym} p \) in the geometrically linear settings, respectively.

In a purely phenomenological context, we have another way to measure the incompatibility of the plastic distortion \( F_p \) itself via the so-called dislocation density tensor \( \text{Curl}_x F_p(x) \) (see for instance [56, 99]). Following the works of Davini-Parry [31], Cermelli-Gurtin [26] and Epstein [42], it has been shown that the differential operator (the "true dislocation density tensor")\(^6\)

\[ \frac{1}{\det F_p} \left( \text{Curl} F_p \right) F_p^T = \det F_e \left( \text{Curl}_e F_e^{-1} \right) F_e^{-T}, \]

\[ \text{The role of that tensor has been critically discussed in Acharya [1].} \]
A fourth order gradient plasticity model based on Kröner’s incompatibility tensor

(where \( \text{Curl}_C \) means taking the spatial Curl w.r.t. the current configuration) is also form-invariant under arbitrary coordinate transformation of the reference placement (see [26, eq.(1.4) on p.1542]).

This property is easily understood from (1.18), which is invariant under reparametrization of the reference system anyway.

From now on, we assume plastic incompressibility, i.e., \( \det F_p = 1 \) and \( \text{tr} p = 0 \). Either

\[
(\text{Curl}_x F_p) F_p^T \text{ linearized through } F_p = 1 + p \text{ turns into } \text{Curl}_x p \tag{1.19}
\]

or

\[
\mathcal{R}(F_p^T F_p) \text{ linearized through } F_p = 1 + p \text{ turns into } \text{inc}(\text{sym} p). \tag{1.20}
\]

Therefore, in the geometrically linear setting two measures of incompatibility of the infinitesimal plastic distortion \( p \) are used in the literature. Some authors use the tensor \( \text{Curl} p \) (see [21, 22, 55, 99]) while others use \( \text{inc}(\text{sym} p) \) (see [84]).

\[
\begin{array}{ll}
\text{Curl} p = 0 & \Rightarrow p = \nabla \vartheta \\
\Rightarrow \text{inc}(\text{sym} p) = \text{inc}(\text{sym} \nabla \vartheta) = 0
\end{array}
\]

\[
\begin{array}{ll}
\text{inc}(\text{sym} p) = 0 & \Rightarrow \text{sym} p = \text{sym} \nabla \vartheta \\
\Rightarrow p = \nabla \vartheta & \text{but} \\
\Rightarrow p = \nabla \vartheta + A(x), & A(x) \in \mathfrak{so}(3) \\
\Rightarrow \text{Curl} p = 0
\end{array}
\]

Table 2: We need to realize that \( \text{Curl} p \) is a “sharper” incompatibility measure than \( \text{inc}(\text{sym} p) \).

Concerning the invariance of the curvature tensor \( \mathcal{R} \) observed in (1.9), we note that under a change of reference placement \( F_p(x) \rightarrow \bar{F}_p(\xi) \nabla \psi(\xi) \), we obtain directly the form-invariance of the true dislocation density tensor \( (\text{Curl}_x F_p) F_p^T \) as well, meaning that

\[
(\text{Curl}_x F_p) F_p^T = (\text{Curl}_\xi (\bar{F}_p(\xi) \nabla \psi(\xi))) (\bar{F}_p(\xi) \nabla \psi(\xi))^T, \tag{1.21}
\]

where \( \text{Curl}_x \) and \( \text{Curl}_\xi \) are the Curl expressed in coordinates \( x \) and \( \xi \), respectively. Therefore, the expression \( \| (\text{Curl}_x F_p) F_p^T \|^2 \) is also a true scalar quantity. Accordingly, in the linearized setting we consider as in (1.12)

\[
p(x) \rightarrow p(x) + \nabla \vartheta(x) \tag{1.22}
\]

and we obtain directly the invariance

\[
\text{Curl} p(x) = \text{Curl} [p(x) + \nabla \vartheta(x)], \tag{1.23}
\]

similar to (1.12).

Concerning superposition of rotation fields, we note that for \( F_p \rightarrow \mathcal{Q} F_p \) for \( \mathcal{Q} \in \text{O}(3) \) where \( \mathcal{Q} \) is a homogeneous rotation, we have

\[
(\text{Curl}(\mathcal{Q} F_p))(\mathcal{Q} F_p)^T = \mathcal{Q} (\text{Curl} F_p) F_p^T \mathcal{Q}^T. \tag{1.24}
\]

\footnote{Note that Gurtin uses a different definition of the Curl-operator. We have the relation \( F_p = [\text{Curl}_{\text{Gurtin}} F_p]^T \) (see [58]).}
Similarly, in the linearized setting we consider \( p(x) \rightarrow \overline{A} + p(x) \) for every \( \overline{A} \in \mathfrak{so}(3) \) with \( \overline{A} \) a constant skew-symmetric matrix and we get

\[
\text{Curl } p(x) = \text{Curl } [\overline{A} + p(x)] .
\]  

(1.25)

We have the relation

\[
\begin{align*}
\psi(x) &= x + \vartheta(x) \quad \text{and} \quad F_p = 1 + p \\
(\text{Curl } F_p) F_p^T &= 0 \iff F_p = \nabla \psi \quad \equiv \quad \text{Curl } p = 0 \iff p = \nabla \vartheta
\end{align*}
\]  

(1.26)

in simply connected domains (see [61, Section 59]).

The difference between the two incompatibility measures for the linearized setting, inc(sym \( p \)) on the one hand, and Curl \( p \) on the other hand is the invariance property under superposed infinitesimal rotations: while inc(sym \( p \)) allows to \textbf{superpose any inhomogeneous} infinitesimal rotation field \( A(x) \), Curl \( p \) allows to \textbf{superpose only homogeneous} infinitesimal rotation fields \( \overline{A} \).

In single crystal gradient plasticity, it is typically Curl \( F_p \) which is used whereas it is debatable, whether Curl \( F_p \) is a good state-variable for polycrystalline material without texture.

In the following we will use a set of invariance conditions which will allow us to decide between using Curl or inc. It is clear, however, that assuming a set of invariance requirements is already a constitutive requirement and therefore subject to discussion.\(^8\) In all these developments, beyond the discussion on which invariance principles are applied, it is our aim to clearly state and show, which kind of modelling restrictions will be obtained from them.

Our contribution is structured as follows: after introducing in Section 2 some notations, operators and function spaces used throughout the paper, we set the stage in Section 3 with two important invariance conditions on which our model will be tested. Namely, the \textit{gauge-invariance} known as invariance under compatible transformations of the reference system, and a novel rotational invariance postulate for polycrystals, called \textit{micro-randomness}. In Section 4, we first present few models of gradient plasticity with Kröner’s incompatibility tensor which fail our invariance conditions, then we introduce our novel fourth order phenomenological model which, though it fails also the gauge-invariance condition, is invariant w.r.t. a subclass of reparametrizations of the reference configurations, including the infinitesimal conformal group. The new model is then formulated using the convex analytical framework leading to mathematical strong and weak formulations. Finally an existence result for the weak formulation is obtained.

Let us next fix some notations and definitions which will also make the paper more clear and readable.

2. Some notational agreements and definitions

Let \( \Omega \) be a bounded domain in \( \mathbb{R}^3 \) with Lipschitz continuous boundary \( \partial \Omega \), which is occupied by an elastoplastic body in its undeformed configuration. Let \( \Gamma \) be a smooth subset of \( \partial \Omega \) with non-vanishing

\(^8\)Only time-objectivity requirements are not to be discussed.
2-dimensional Hausdorff measure. A material point in $\Omega$ is denoted by $x$ and the time domain under consideration is the interval $[0,T]$. For every $a,b \in \mathbb{R}^3$, we let $(a,b)_{\mathbb{R}^3}$ denote the scalar product on $\mathbb{R}^3$ with associated vector norm $\|a\|^2_{\mathbb{R}^3} = (a,a)_{\mathbb{R}^3}$. We denote by $\mathbb{R}^{3\times3}$ the set of real $3 \times 3$ tensors. The standard Euclidean scalar product on $\mathbb{R}^{3\times3}$ is given by $\langle A,B \rangle_{\mathbb{R}^{3\times3}} = \text{tr} (AB^T)$, where $B^T$ denotes the transpose tensor of $B$. Thus, the Frobenius tensor norm is $\|A\|^2 = \langle A,A \rangle_{\mathbb{R}^{3\times3}}$. In the following we omit the subscripts $\mathbb{R}^3$ and $\mathbb{R}^{3\times3}$. The identity tensor on $\mathbb{R}^{3\times3}$ will be denoted by $\mathbf{1}$, so that $\text{tr}(A) = \langle A, \mathbf{1} \rangle$. We let $\text{GL}(3) := \{ X \in \mathbb{R}^{3\times3} \mid \det(X) \neq 0 \}$ denote the group of invertible $3 \times 3$ square matrices; $\text{GL}^+(3) := \{ X \in \mathbb{R}^{3\times3} \mid \det(X) > 0 \}$; $\text{SO}(3) := \{ X \in \text{GL}(3) \mid X X^T = \mathbf{1}, \det[X] = 1 \}$ is the Lie Group of rotations in $\mathbb{R}^3$ whose Lie Algebra is the set $\mathfrak{so}(3) := \{ X \in \mathbb{R}^{3\times3} \mid X^T = -X \}$ of skew-symmetric tensors. We let $\text{Sym}(3) := \{ X \in \mathbb{R}^{3\times3} \mid X^T = X \}$ denote the set of symmetric tensors and $\mathfrak{sl}(3) := \{ X \in \mathbb{R}^{3\times3} \mid \text{tr}(X) = 0 \}$ be the Lie Algebra of traceless tensors. For every $X \in \mathbb{R}^{3\times3}$, we set $\text{sym}(X) = \frac{1}{2}(X + X^T)$, $\text{skew}(X) = \frac{1}{2}(X - X^T)$ and $\text{dev}(X) = X - \frac{1}{2}\text{tr}(X)\mathbf{1} \in \mathfrak{sl}(3)$ for the symmetric part, the skew-symmetric part and the deviatoric part of $X$, respectively. Quantities which are constant in space will be denoted with an overbar, e.g., $\bar{A} \in \mathfrak{so}(3)$ for the function $A : \mathbb{R}^3 \to \mathfrak{so}(3)$ which is constant with constant $\bar{A}$.

The body is assumed to undergo deformations. Its behaviour is governed by a set of equations and constitutive relations. Below is a list of variables and parameters used throughout the paper:

- $\varphi$ is the deformation of the body;
- $u(x,t) = \varphi(x,t) - x$ is the displacement of the macroscopic material points;
- $F = \nabla \varphi = \mathbf{1} + \nabla u$ is the deformation gradient;
- $F_p = \mathbf{1} + p$ is the plastic distortion which is a non-symmetric tensor with unit determinant, that is, $F_p \in \text{SL}(3)$;
- $F_e = \mathbf{1} + e$ is the elastic distortion which is a non-symmetric tensor;
- $C_p := F_p^T F_p = \mathbf{1} + \varepsilon_p + \ldots$ is the positive definite plastic metric;
- $C_e := F_e^T F_e = \mathbf{1} + \varepsilon_e + \ldots$ is the positive definite elastic strain tensor;
- $p$ is the infinitesimal plastic distortion variable which is a non-symmetric second order tensor, incapable of sustaining volumetric changes; that is, $p \in \mathfrak{sl}(3)$. The tensor $p$ represents the average plastic slip; $p$ is not gauge-invariant, while the rate $\dot{p}$ is;
- $e = \nabla u - p$ is the infinitesimal elastic distortion which is a non-symmetric second order tensor and is a state-variable;
- $\varepsilon_p = \text{sym} p$ is the symmetric infinitesimal plastic strain tensor, which is also trace free, $\varepsilon_p \in \mathfrak{sl}(3)$; $\varepsilon_p$ is not gauge-invariant; the rate $\dot{\varepsilon}_p = \text{sym} \dot{p}$ is gauge-invariant; $\varepsilon_p$ is not a state-variable;
- skew $p$ is called plastic rotation or plastic spin and is not a state-variable;
- $\varepsilon_e = \text{sym}(\nabla u - p)$ is the symmetric infinitesimal elastic strain tensor and is a state-variable;
\( \sigma \) is the Cauchy stress tensor which is a symmetric second order tensor and is gauge-invariant;

\( \sigma_0 \) is the initial yield stress for plastic strain and is gauge-invariant;

\( \sigma_y \) is the current yield stress for plastic strain and is gauge-invariant;

\( f \) is the body force;

\( \text{Curl } p = - \text{Curl } e = \alpha \) is Nye’s dislocation density tensor (see (1.18) for the definition of \( \alpha \)), satisfying the so-called Bianchi identities \( \text{Div } \alpha = 0 \) and is gauge-invariant;

\( R \) is the Riemann-Christoffel curvature tensor, see (1.5);

\( \|R\|^2 \) is the Lanczos-type scalar;

\( \text{inc}(\text{sym } p) = \text{inc}(\varepsilon_p) = - \text{inc}(\varepsilon_e) \) is Kröner’s second order incompatibility tensor and is gauge-invariant;

\( \gamma_p = \int_0^t \|\text{sym } \dot{p}\| \, ds \) is the accumulated equivalent plastic strain and is gauge-invariant;

\( \tilde{\gamma}_p = \int_0^t \|\dot{p}\| \, ds \) is the accumulated equivalent plastic distortion and is gauge-invariant.

For isotropic media, the fourth order isotropic elasticity tensor \( C_{\text{iso}} : \text{Sym}(3) \to \text{Sym}(3) \) is given by

\[
C_{\text{iso}} X = 2 \mu \text{ dev sym } X + \kappa \text{ tr}(X) \mathbb{1} = 2 \mu \text{ sym } X + \lambda \text{ tr}(X) \mathbb{1}
\]  

(2.1)

for any second-order tensor \( X \), where \( \mu \) and \( \lambda \) are the Lamé moduli satisfying

\[
\mu > 0 \quad \text{and} \quad 3\lambda + 2\mu > 0,
\]  

(2.2)

and \( \kappa > 0 \) is the bulk modulus. These conditions suffice for pointwise ellipticity of the elasticity tensor in the sense that there exists a constant \( m_0 > 0 \) such that

\[
\forall X \in \mathbb{R}^{3 \times 3} : \quad \langle \text{sym } X, C_{\text{iso}} \text{ sym } X \rangle \geq m_0 \|\text{sym } X\|^2.
\]  

(2.3)

For every \( X \in C^1(\Omega, \mathbb{R}^{3 \times 3}) \) with rows \( X_1, X_2, X_3 \), we use in this paper the definition of Curl \( X \) in \([99, 128]\):

\[
\text{Curl } X = \begin{pmatrix}
\text{curl } X_1 \\
\text{curl } X_2 \\
\text{curl } X_3
\end{pmatrix} \in \mathbb{R}^{3 \times 3},
\]  

(2.4)

for which \( \text{Curl } \nabla v = 0 \) for every \( v \in C^2(\Omega, \mathbb{R}^3) \). Notice that the definition of Curl \( X \) above is such that \( (\text{Curl } X)^T a = \text{curl } (X^T a) \) for every \( a \in \mathbb{R}^3 \) and this clearly corresponds to the transpose of the Curl of a tensor as defined in \([55, 58]\).
A fourth order gradient plasticity model based on Kröner’s incompatibility tensor

For
\[
\begin{pmatrix}
0 & -a_3 & a_2 \\
a_3 & 0 & -a_1 \\
-a_2 & a_1 & 0
\end{pmatrix} \in \mathfrak{so}(3),
\]
we consider the operator \(\text{axl}: \mathfrak{so}(3) \to \mathbb{R}^3\) and \(\text{anti}: \mathbb{R}^3 \to \mathfrak{so}(3)\) through
\[
\text{axl}(A) := (a_1, a_2, a_3)^T, \quad A. v = (\text{axl}(A) \times v, \quad (\text{anti}(v))_{ij} = \varepsilon_{ijk} v_k, \quad \forall v \in \mathbb{R}^3, \quad (2.5)
\]
\[
(axl(A))_k = -\frac{1}{2} \sum_{i,j=1}^{3} \varepsilon_{ijk} A_{ij} = \frac{1}{2} \sum_{i,j=1}^{3} \varepsilon_{kij} A_{ji}, \quad (2.6)
\]
\[
A_{ij} = \sum_{k=1}^{3} -\varepsilon_{ijk} (axl(A))_k =: \text{anti}(axl(A))_{ij}, \quad (2.7)
\]
\[
axl(\text{anti}(v))_k = v_k, \quad (2.8)
\]
where \(\varepsilon_{ijk}\) is the totally antisymmetric third order Levi-Civita permutation tensor defined by
\[
\varepsilon_{ijk} := \begin{cases} 
1 & \text{if } \{i, j, k\} = \{1, 2, 3\}, \{2, 3, 1\} \text{ or } \{3, 1, 2\}, \\
-1 & \text{if } \{i, j, k\} = \{2, 1, 3\}, \{1, 3, 2\} \text{ or } \{3, 2, 1\}, \\
0 & \text{if an index is repeated.}
\end{cases}
\]

Hence, the operators \(\text{axl}: \mathfrak{so}(3) \to \mathbb{R}^3\) and \(\text{anti}: \mathbb{R}^3 \to \mathfrak{so}(3)\) are canonical identifications of \(\mathfrak{so}(3)\) and \(\mathbb{R}^3\). Notice that,
\[
(axl \text{ skew } A)_k = \frac{1}{2} \sum_{i,j=1}^{3} \varepsilon_{kij} \text{ skew } (A)_{ji} = \frac{1}{4} \sum_{i,j=1}^{3} \varepsilon_{kij} A_{ji} - \frac{1}{4} \sum_{i,j=1}^{3} \varepsilon_{kij} A_{ji}
\]
\[
= \frac{1}{2} \sum_{i,j=1}^{3} \varepsilon_{kij} A_{ji} \quad \forall A \in \mathbb{R}^{3 \times 3}. \quad (2.9)
\]

The following function spaces and norms will also be used later.
\[
\begin{align*}
H(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) & := \left\{ X \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{Curl } X \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \right\}, \\
\|X\|_{H(\text{Curl}; \Omega)}^2 & := \|X\|_{L^2(\Omega)}^2 + \|\text{Curl } X\|_{L^2(\Omega)}^2, \quad \forall X \in H(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}), \quad (2.10)
\end{align*}
\]
for \(E := \mathfrak{sl}(3)\) or \(\text{Sym} \cap \mathfrak{sl}(3)\).

We also consider the space
\[
H_0(\text{Curl}; \Omega, \Gamma, \mathbb{R}^{3 \times 3}) \quad (2.11)
\]
as the completion in the norm in (2.10) of the space \(\{ q \in C^\infty(\Omega, \Gamma, \mathbb{R}^{3 \times 3}) \mid q \times n|_\Gamma = 0 \} \). Therefore, this space generalizes the tangential Dirichlet boundary condition
\[
q \times n|_\Gamma = 0 \quad (2.12)
\]
to be satisfied by the plastic distortion $p$ or the plastic strain $\varepsilon_p := \text{sym } p$. Whenever, $\Gamma = \partial \Omega$, we simply write $H_0(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3})$. The space

$$H_0(\text{Curl}; \Omega, \Gamma, \mathbb{E})$$

is defined as in (2.10).

The divergence operator $\text{Div}$ on second order tensor-valued functions is also defined row-wise as

$$\text{Div } X = \begin{pmatrix} \text{div } X_1 \\ \text{div } X_2 \\ \text{div } X_3 \end{pmatrix}. \quad (2.13)$$

Further properties of Kröner’s incompatibility tensor $\text{inc}$ can be found in the appendix.

3. Discussion of some invariance conditions in plasticity

3.1. Gauge-invariance - invariance under compatible transformations of the reference system

Since the modelling should be invariant with respect to the used coordinates system, we may introduce the gauge-invariance condition.

Consider again the multiplicative split $F(x) = F_e(x)F_p(x)$ and perform a compatible change of the reference configuration, i.e., set $x = \psi(\xi)$. Then we have upon transforming to new coordinates

$$F(\psi(\xi)) \nabla_\xi \psi(\xi) = F_e(\psi(\xi)) F_p(\psi(\xi)) \nabla_\xi \psi(\xi). \quad (3.1)$$

Therefore we require our new model to be form-invariant under

$$
\begin{align*}
F(x) &\to F(\psi(\xi)) \nabla_\xi \psi(\xi) &\forall \psi \in C^1(\mathbb{R}^3, \mathbb{R}^3) \\
F_p(x) &\to F_p(\psi(\xi)) \nabla_\xi \psi(\xi) &\text{(Finite Gauge-Invariance)}
\end{align*}
$$

Performing a geometrical linearization, we obtain

$$F(x) = F_e(x)F_p(x) \quad \to \quad \nabla u = e(x) + p(x)$$

and the finite gauge-invariance (FGI) translates into direct invariance under

$$
\begin{align*}
\nabla u(x) &\to \nabla u(\xi) + \nabla \vartheta(\xi) &\forall \vartheta \in C^1(\mathbb{R}^3, \mathbb{R}^3) \\
p(x) &\to p(\xi) + \nabla \vartheta(\xi) &\text{(Linear Gauge-Invariance)}
\end{align*}
$$

which is also known as translational gauge-invariance (see Lazar [74, 75, 76]).
A fourth order gradient plasticity model based on Kröner’s incompatibility tensor

Figure 1: The micro-random model does not resolve a scale smaller than $\hat{L}_c$ (blue-filled balls)! Inside the blue-filled balls, we have crystallites; if we want to model what happens inside there, we can still try to model this with isotropy assumption. This is our isotropic Curl $p$-model with spin (see Table 6). In reality however, the orientation of the crystallites matters.

3.2. Micro-randomness: a novel rotational invariance postulate for polycrystals

Polycrystals can be viewed as random aggregates of single crystals which, at sufficiently large scales can be viewed as isotropic.
Imagine a given initial distribution \( F_p(x,0) \) of grains and subject the polycrystal to a given mechanical loading which alters the plastic state. The result will be recorded in the history \( t \rightarrow F_p(x,t) \).

Now consider a randomly rotated initial distribution of grains and plastic distortions via
\[
\tilde{F}_p(x,0) := Q(x)F_p(x,0) \quad \text{with} \quad Q(x) \in \text{SO}(3).
\] (3.2)

At a sufficiently large scale we are not able to discern this rotational rearrangement and we are led to assume that the new plastic history under the same given loading as before should be
\[
t \rightarrow \tilde{F}_p(x,t) := Q(x)F_p(x,t).
\] (3.3)

This is essentially a new invariance requirement to be imposed on our model for the polycrystal. It means that, up to the initially different inhomogeneous rotation of the grains, the response is the same. Since rotations are involved one might take this as a statement of classical isotropy. However, this would be misguided since classical isotropy is concerned with rigidly rotating the whole (polycrystalline) sample, while here each individual grain is rotated differently\(^9\) (see explanation in Figure 1).

Considering now the geometrically linear setting, we compare the initial infinitesimal plastic distortion \( p(x,0) \) with solution \( t \rightarrow p(x,t) \) versus \( p(x,0) + A(x) \) with its time evolution \( t \rightarrow \tilde{p}(x,t) \). Our micro-randomness invariance condition postulates in the geometrically linear setting that
\[
p(x,0) \rightarrow \tilde{p}(x,0) = p(x,0) + A(x) \Rightarrow p(x,0) + A(x) \forall t > 0 \quad \text{(Linear Micro-Random)} \tag{LMR}
\]
and in the finite deformation setting that
\[
F_p(x,0) \rightarrow \tilde{F}_p(x,0) = Q(x)F_p(x,0) \Rightarrow F_p(x,0) \rightarrow \tilde{F}_p(x,t) = Q(x)F_p(x,t) \forall t > 0 \quad \text{(Finite Micro-Random)} \tag{FMR}
\]

In addition, we are aware of the fact that determining exact initial conditions for the rotations of grains in a polycrystal is practically impossible. Therefore, the influence of considering different initial grain distributions should be minimized in order to obtain a suitable effective model. Our micro-randomness invariance condition ensures that the effect of different initial conditions shows only as an "offset" of an otherwise unique response, as seen above.

Notice that
\[
F(x) = F_e(x)F_p(x) = F_e(x)Q(x)^TQ(x)F_p(x) \quad \text{with} \quad Q(x) = \exp(A(x)),
\] (3.4)

\[
\nabla u = e(x) + p(x) = e + A^T(x) + A(x) + p(x) = 0
\]

\(^9\)Rotating grains against each other (see Neff et al. [105]) in a polycrystal changes the eigen-stresses along grain boundaries. Therefore, our new invariance requirement cannot be a fundamental law of nature but may rather serve to concentrate on some effective macroscopic features in a homogenized model.
A fourth order gradient plasticity model based on Kröner’s incompatibility tensor

thus the invariance condition connected to micro-randomness reads in the finite strain case

$$(F, F_e, F_p) \rightarrow (F, F_e Q^T(x), QF_p(x)) \quad \forall Q(x) \in \text{SO}(3),$$

while in the geometrically linear context, we need to require the invariance

$$(\nabla u, e, p) \rightarrow (\nabla u, e + A^T(x), A(x) + p(x)) \quad \forall A(x) \in \mathfrak{s}(3).$$

3.3. Isotropy in geometrically linear models

While the above invariance conditions can be characterized by additive operators, for classical isotropy we need the group of rotations $Q \in \text{O}(3)$. We define isotropy in geometrically linear models to be form-invariance under simultaneous change of spatial and referential coordinates by a rigid rotation. In this case, scalar functions $h : \mathbb{R}^3 \rightarrow \mathbb{R}$, vector fields $\phi : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ and second order tensor fields $S : \mathbb{R}^3 \rightarrow \mathbb{R}^{3 \times 3}$ are transformed as follows:

$$h \rightarrow h^\sharp \quad \text{with} \quad h^\sharp(\xi) := h(Q^T \xi),$$

$$\phi \rightarrow \phi^\sharp \quad \text{with} \quad \phi^\sharp(\xi) := Q \phi(Q^T \xi),$$

$$S \rightarrow S^\sharp \quad \text{with} \quad S^\sharp(\xi) := Q S(Q^T \xi) Q^T.$$

It can be shown (see [92]) that

$$\text{Curl}_\xi [p^\sharp(\xi)] = Q (\text{Curl}_x p(x)) Q^T \quad \text{and} \quad \text{inc}_\xi [\text{sym} p^\sharp(\xi)] = Q \text{inc}_x [\text{sym} p(x)] Q^T.$$ (3.8)

Therefore, both our incompatibility measures are properly isotropic and therefore all our presented models, based on $\text{Curl} \ p$ or $\text{inc}(\text{sym} \ p)$, respectively, are fully isotropic.

A summary of the invariance conditions for infinitesimal gradient plasticity is presented in Table 3.

| Objectivity/Linearized frame-indifference: | $\nabla u \rightarrow A + \nabla u$, $A \in \mathfrak{s}(3)$ |
| Linearized gauge-invariance: | $\nabla u \rightarrow \nabla u + \nabla \vartheta$, $\vartheta \in C^1(\mathbb{R}^3, \mathbb{R}^3)$ |
| Linearized micro-randomness: | $p \rightarrow p + A(x)$, $A(x) \in \mathfrak{s}(3)$ |
| Isotropy: | $h : \mathbb{R}^3 \rightarrow \mathbb{R} \rightarrow h^\sharp \quad \text{with} \quad h^\sharp(\xi) := h(Q^T \xi)$, $Q \in \text{O}(3)$ |
| | $\phi : \mathbb{R}^3 \rightarrow \mathbb{R}^3 \rightarrow \phi^\sharp \quad \text{with} \quad \phi^\sharp(\xi) := Q \phi(Q^T \xi)$, $Q \in \text{O}(3)$ |
| | $S : \mathbb{R}^3 \rightarrow \mathbb{R}^{3 \times 3} \rightarrow S^\sharp \quad \text{with} \quad S^\sharp(\xi) := Q S(Q^T \xi) Q^T$ |

Table 3: Invariance conditions for infinitesimal gradient plasticity
4. Some models of gradient plasticity with Kröner’s incompatibility tensor

Before we introduce and analyze our "ideal" model designed from the set of requirements presented in the introduction, we found that it is more interesting to first present those few models we first considered with an emphasis on the difficulties and shortcomings of those models both from the mechanical and mathematical points of view. Let us first make it clear that the approach used to analyze those models as well as our model in Section 4.3 is through a convex analytical framework and variational inequalities developed in Han-Reddy [60] for classical plasticity and quite often used for models of gradient plasticity (see [33, 122, 99, 36, 40]), as well.

4.1. An irrotational model with linear kinematic hardening

In this section, we present a model with linear kinematic hardening and Kröner’s incompatibility tensor where the plastic variable is symmetric i.e., a model with no plastic spin. The goal is to find the displacement field \( \mathbf{u} \) and the infinitesimal plastic strain \( \varepsilon_p \) in some suitable function spaces such that the content of Table 4 holds.

| Additive split of distortion: \( \nabla \mathbf{u} = \varepsilon_e + p \) |
| Additive split of strain: \( \text{sym} \nabla \mathbf{u} = \varepsilon_e + \varepsilon_p \) |
| Equilibrium: \( \text{Div} \sigma + f = 0 \) with \( \sigma = C_{\text{iso}} \varepsilon_e \) |
| Free energy: \( \frac{1}{2} \langle C_{\text{iso}} \varepsilon_e, \varepsilon_e \rangle + \frac{1}{2} \mu_k k_1 \| \varepsilon_p \|_2^2 + \frac{1}{2} \mu \hat{L}_c \| \text{inc}(\varepsilon_p) \|_2^2 \) |
| Yield condition: \( \phi(\Sigma_E) := \| \text{dev} \Sigma_E \| - \sigma_0 \leq 0 \) where \( \Sigma_E := \sigma + \Sigma_{\text{kin}} + \Sigma_{\text{inc}} \) with \( \Sigma_{\text{kin}} := -\mu k_1 \varepsilon_p, \Sigma_{\text{inc}} := -\mu \hat{L}_c \text{inc}(\text{inc} \varepsilon_p) \in \text{Sym}(3) \) |
| Dissipation inequality: \( \int_\Omega \langle \Sigma_E, \dot{\varepsilon}_p \rangle \, dx \geq 0 \) |
| Dissipation function: \( D(q) := \sigma_0 \| q \| \) |
| Flow law in primal form: \( \Sigma_E \in \partial D(\dot{\varepsilon}_p) \) |
| Flow law in dual form: \( \dot{\varepsilon}_p = \lambda \| \text{dev} \Sigma_E \|, \lambda = \| \dot{\varepsilon}_p \| \) |
| KKT conditions: \( \lambda \geq 0, \phi(\Sigma_E) \leq 0, \lambda \phi(\Sigma_E) = 0 \) |
| Boundary conditions for \( \varepsilon_p \): to be specified |
| Function space for \( \varepsilon_p \): \( \varepsilon_p(t, \cdot) \in L^2(\Omega, \text{Sym}(3)), \text{inc}(\varepsilon_p) \in L^2(\Omega, \text{Sym}(3)) \) |

Table 4: The model with linear kinematic Prager-type hardening and Kröner’s incompatibility tensor. The boundary conditions on \( \varepsilon_p \) cannot be specified from the structure of the model. The problem with this model is the presence of the norm \( \| \varepsilon_p \|^2 \) which is not linearized gauge-invariant. A careful analysis of the model in the spirit of Section 4.3 will lead to single out the necessity of an \( L^2 \)-control of Curl \( \varepsilon_p \), which is also not a priori controlled in the model. Altogether, well-posedness of the model remains unclear. A modified version of this model is presented in Table 5. This model is micro-random i.e., invariant w.r.t. \( p \to p + A(x), A(x) \in so(3) \), but not linearized gauge-invariant, i.e., not invariant w.r.t. \( p \to p + \nabla \vartheta, \vartheta \in C^1(\mathbb{R}^3, \mathbb{R}) \).

4.2. A fully isotropic model with isotropic hardening and plastic spin

The model is completely described in Table 6.
A fully isotropic model with isotropic hardening and plastic spin. The model is fully isotropic since it is form-invariant under the $\mathcal{U}$-transformation defined in (3.7). The model is also linearized gauge-invariant i.e., invariant w.r.t. $p \rightarrow p + \nabla \vartheta$, $\vartheta \in \mathcal{C}^1(\mathbb{R}^3, \mathbb{R})$, but not micro-random i.e., not invariant w.r.t. $p \rightarrow p + A(x)$, $A(x) \in \mathfrak{so}(3)$.

Table 5: The model with linear kinematic Prager-type hardening and Kröner’s incompatibility tensor. The simple regularization term $\|\text{Curl } \epsilon_p\|^2$ allows to justify the boundary conditions on $\epsilon_p$. The problem with this model is the presence of the norms $\|\epsilon_p\|^2$ and $\|\text{Curl } \epsilon_p\|^2$ which are both not linearized gauge-invariant. Altogether, well-posedness of this modified model is obtained as in Section 4.3, with the difference that uniqueness of the weak solution is obtained without any additional regularity assumption. This model is micro-random i.e., invariant w.r.t. $p \rightarrow p + A(x)$, $A(x) \in \mathfrak{so}(3)$, but not linearized gauge-invariant, i.e., not invariant w.r.t. $p \rightarrow p + \nabla \vartheta$, $\vartheta \in \mathcal{C}^1(\mathbb{R}^3, \mathbb{R})$. 

Table 6: A fully isotropic model with isotropic hardening and plastic spin. The model is fully isotropic since it is form-invariant under the $\mathcal{U}$-transformation defined in (3.7). The model is also linearized gauge-invariant i.e., invariant w.r.t. $p \rightarrow p + \nabla \vartheta$, $\vartheta \in \mathcal{C}^1(\mathbb{R}^3, \mathbb{R})$, but not micro-random i.e., not invariant w.r.t. $p \rightarrow p + A(x)$, $A(x) \in \mathfrak{so}(3)$.

4.3. An irrotational model with isotropic hardening

In this section we discuss a variant of the previous model with linear kinematic hardening replaced by isotropic hardening. The new model will be invariant under Linear Referential Isotropy (LRIso), Linear Micro-Random (LMR), Linear Gauge-Invariance (LGI), Linear Elastic Objectivity, Linear Elastic Isotropy.

4.3.1. Derivation of the model

The balance equation. The conventional macroscopic force balance leads to the equation of equilibrium

$$\text{Div } \sigma + f = 0$$

in which $\sigma$ is the infinitesimal symmetric Cauchy stress and $f$ is the body force.

Constitutive equations. The constitutive equations are obtained from a free energy imbalance together with a flow law that characterizes plastic behaviour. The total strain $\varepsilon$ is additively decomposed into elastic and plastic components $\varepsilon_e$ and $\varepsilon_p$, so that

$$\varepsilon = \varepsilon_e + \varepsilon_p$$

with the plastic strain incapable of sustaining volumetric changes; that is, $\text{tr } \varepsilon_p = 0$.

The strain-displacement relation is given by

$$\varepsilon = \text{sym } \nabla u = \frac{1}{2}(\nabla u + \nabla u^T).$$

Free energy density: In this model the free-energy density is considered in the additively separated form

$$W(u, \varepsilon_p, D^2\varepsilon_p, \gamma_p) := W_e(\varepsilon_e) + W_{\text{inc}}(D^2\varepsilon_p) + W_{\text{iso}}(\gamma_p),$$

where

$$W_e(\varepsilon_e) := \frac{1}{2} \langle \varepsilon_e, C_{iso} \varepsilon_e \rangle = \mu \| \text{sym } \nabla u - \varepsilon_p \|^2 + \frac{1}{2} \lambda \text{tr}[\nabla u - \varepsilon_p]^2,$$

$$W_{\text{inc}}(D^2\varepsilon_p) := \frac{1}{2} \mu \tilde{L}_c^4 \| \text{inc } \varepsilon_p \|^2 = \frac{1}{2} \mu \tilde{L}_c^4 \| \text{Curl } [(\text{Curl } \varepsilon_p)^T] \|^2,$$

$$W_{\text{iso}}(\gamma_p) := \frac{1}{2} \mu k^2 |\gamma_p|^2,$$

and $\lambda, \mu$ are the Lamé moduli with $\mu > 0$ and $3\lambda + 2\mu > 0$, $\tilde{L}_c \geq 0$ is an energetic length scale and $k \geq 0$ is a positive non-dimensional isotropic hardening constant, $\gamma_p$ is the isotropic hardening variable (the accumulated equivalent plastic strain).
From the local free energy imbalance
\[
\frac{d}{dt} W \leq \langle \sigma, \nabla u \rangle = \langle \sigma, \dot{\varepsilon} \rangle \iff \frac{d}{dt} W - \langle \sigma, \dot{\varepsilon} \rangle - \langle \sigma, \dot{\varepsilon}_p \rangle \leq 0 \\
\iff \frac{d}{dt} W(u, \varepsilon_p, D^2 \varepsilon_p, \gamma_p) \leq 0 \quad \text{for } u \text{ fixed}
\]
where the second equivalence is obtained using arguments from thermodynamics which give the elasticity relation
\[
\sigma = C_{iso} \varepsilon = 2\mu (\text{sym} \nabla u - \varepsilon_p) + \lambda \text{tr}(\text{sym} \nabla u - \varepsilon_p) \mathbf{1} . \tag{4.6}
\]
Therefore, we get
\[
\langle \sigma, \dot{\varepsilon}_p \rangle - \mu \hat{L}_c^4 \langle \text{inc} \varepsilon_p, \text{inc} \dot{\varepsilon}_p \rangle - \mu k_2 \gamma_p \dot{\gamma}_p \geq 0 . \tag{4.7}
\]
Now, integrating (4.7), we arrive at
\[
0 \leq \int_{\Omega} \left[ \langle \sigma, \dot{\varepsilon}_p \rangle - \mu \hat{L}_c^4 \langle \text{inc} \varepsilon_p, \dot{\varepsilon}_p \rangle - \mu k_2 \gamma_p \dot{\gamma}_p - \sum_{i=1}^{3} \text{div} \left( \mu \hat{L}_c^4 \dot{\varepsilon}_{pi} \times [\text{Curl inc} \varepsilon_p]_i \right) \right] dx \\
- \sum_{i=1}^{3} \text{div} \left( \mu \hat{L}_c^4 [\text{Curl} \dot{\varepsilon}_p]_i^T \times [\text{inc} \varepsilon_p]_i \right) dx \\
= \int_{\Omega} \left[ \langle \sigma - \mu \hat{L}_c^4 \text{inc} \varepsilon_p, \dot{\varepsilon}_p \rangle - \mu k_2 \gamma_p \dot{\gamma}_p \right] dx \\
- \sum_{i=1}^{3} \mu \hat{L}_c^4 \int_{\partial \Omega} \langle \dot{\varepsilon}_{pi} \times [\text{Curl inc} \varepsilon_p]_i^T, n \rangle dS - \sum_{i=1}^{3} \mu \hat{L}_c^4 \int_{\partial \Omega} \langle [\text{Curl} \dot{\varepsilon}_p]_i^T \times [\text{inc} \varepsilon_p]_i, n \rangle dS . \tag{4.8}
\]
In order to obtain a global reduced dissipation inequality one needs to choose suitable boundary conditions for which the two equations below are satisfied
\[
\sum_{i=1}^{3} \int_{\partial \Omega} \langle \dot{\varepsilon}_{pi} \times n, [\text{Curl inc} \varepsilon_p]_i^T \rangle dS = 0 . \tag{4.9}
\]
\[
\sum_{i=1}^{3} \int_{\partial \Omega} \langle [\text{Curl} \dot{\varepsilon}_p]_i^T \times n, [\text{inc} \varepsilon_p]_i \rangle dS = 0 . \tag{4.10}
\]
The simplest lower order boundary conditions to satisfy (4.9) and (4.10) are
\[
\varepsilon_p \times n|_{\partial \Omega} = 0 \quad \text{and} \quad [\text{Curl} \varepsilon_p]^T \times n|_{\partial \Omega} = 0 . \tag{4.11}
\]
Other possible boundary conditions to satisfy the equations (4.9) and (4.10) are given in the table below.

However, these boundary conditions cannot be mathematically justified from the free-energy density $W$ considered so far: both terms in (4.9) and (4.10) are not automatically well-defined as boundary traces. In fact, one needs to show that $\varepsilon_p \in H(\text{Curl})$ and $(\text{Curl} \varepsilon_p)^T \in H(\text{Curl})$. This information is missing from the energy. We only know that $\varepsilon_p \in L^2$ (due to isotropic hardening) and $\text{inc} \varepsilon_p = \text{Curl}[(\text{Curl} \varepsilon_p)^T] \in L^2$. The missing piece of information to proceed is $\text{Curl} \varepsilon_p \in L^2$. 

\[\text{A fourth order gradient plasticity model based on Kröner’s incompatibility tensor}\]
Table 7: Possible boundary conditions for (4.9) and (4.10) to be satisfied.

So, one needs to modify the model by adding a new regularizing term in the free-energy density $W$, which is physically meaningful in the sense that it does satisfy some invariance properties. The unmodified model is summarized in Table 8.

We will consider the additional term

$$W_{\text{curl}}(Dp) := \frac{1}{2} \mu L_c^2 \|\text{dev sym Curl } \epsilon_p\|^2,$$

which is motivated in the following section.
4.3.2. Conformal gauge-invariance - the regularization term \( \text{dev sym Curl } \varepsilon_p \)

We will see subsequently that the model with the regularizing term \( \text{dev sym Curl } \varepsilon_p \) allows for a mathematical existence proof. However, what about the invariance conditions, notably gauge-invariance? It is easy to see that

\[
p \rightarrow \text{dev sym Curl } \varepsilon_p = \text{dev sym Curl sym } p
\]

is micro-random while it is not linear gauge-invariant, i.e.,

\[
p \rightarrow p + \nabla \vartheta \quad \text{dev sym Curl sym}(\nabla \vartheta + p) \neq \text{dev sym Curl sym } p, \quad \forall \vartheta \in C^1(\Omega, \mathbb{R}^3).
\]

Let us now determine those mappings \( \vartheta : \mathbb{R}^3 \to \mathbb{R}^3 \) which are still “allowed” for gauge-invariance, in the sense that

\[
\text{dev sym Curl sym}(\nabla \vartheta + p) = \text{dev sym Curl sym } p.
\]

Automatically, these mappings satisfy the identity \( \text{inc}(\text{sym } \nabla \vartheta) = 0 \). Moreover, by linearity we should have

\[
\text{dev sym Curl sym } \nabla \vartheta = 0.
\]

Since, however, \( \text{tr}(\text{Curl } S) = 0 \) for all smooth symmetric tensor fields \( S \in \text{Sym}(3) \) (see (5.3) in the appendix), the latter is equivalent to

\[
\text{sym Curl sym } \nabla \vartheta = 0.
\]

This implies that for some non-constant skew-symmetric tensor field \( A : \Omega \to \mathfrak{so}(3) \) we have

\[
\text{Curl sym } \nabla \vartheta(x) = A(x) \iff (\text{Curl sym } \nabla \vartheta)(x) = - A(x).
\]

Taking the Curl on both sides leads to

\[
\text{Curl}[(\text{Curl sym } \nabla \vartheta)(x)] = - \text{Curl } A(x) \iff 0 = \text{inc}(\text{sym } \nabla \vartheta) = - \text{Curl } A(x).
\]

Thus, \( A(x) = \overline{A} \) is a constant skew-symmetric matrix, according to an observation in [92]. Reinserting into (4.15), we must have

\[
\text{Curl sym } \nabla \vartheta(x) = \overline{A}.
\]

We observe that (see [102])

\[
\text{Curl}(\zeta(x_1, x_2, x_3) \cdot 1) = \begin{pmatrix}
0 & -\zeta_3 & \zeta_2 \\
\zeta_3 & 0 & -\zeta_1 \\
-\zeta_2 & \zeta_1 & 0
\end{pmatrix} \zeta : \mathbb{R}^3 \to \mathbb{R}
\]

and with \( \zeta(x_1, x_2, x_3) = a x_1 + b x_2 + c x_3 \), we obtain

\[
\text{Curl}((ax_1 + bx_2 + cx_3) \cdot 1) = \begin{pmatrix}
0 & -c & b \\
c & 0 & -a \\
-b & a & 0
\end{pmatrix}.
\]
Hence, a solution to (4.17) can be obtained in the format
\[ \text{sym} \nabla \vartheta(x_1, x_2, x_3) = \zeta(x_1, x_2, x_3) \cdot 1. \] (4.18)

On taking again the deviatoric part of the latter we arrive at
\[ \text{dev sym} \nabla \vartheta(x_1, x_2, x_3) = 0. \] (4.19)

This is equivalent to
\[ \nabla \vartheta(x) = \zeta(x_1, x_2, x_3) \cdot 1 + A(x_1, x_2, x_3) \quad \text{with} \quad A : \mathbb{R}^3 \to \mathfrak{so}(3). \] (4.20)

The solution to (4.19) can be given in closed form. In fact, taking Curl on both sides of (4.20), together with the fact that Curl(\(\zeta(x_1, x_2, x_3) \cdot 1\)) \(\in \mathfrak{so}(3)\) one gets \(A(x_1, x_2, x_3) = \hat{A} \in \mathfrak{so}(3)\) constant skew-symmetric matrix. Also, using the operators axl and anti defined in (2.5), a general solution to (4.19) is obtained in the form
\[ \phi_c(x) := \frac{1}{2} \left( 2\langle \text{axl}(\hat{W}), x \rangle x - \text{axl}(\hat{W}) \|x\|^2 \right) + \left[ \hat{\zeta} \cdot 1 + \hat{A} \right] x + \hat{\eta}, \] (4.21)

where \(\hat{A}, \hat{W} \in \mathfrak{so}(3)\) are arbitrary constant skew-symmetric matrices and \(\hat{\zeta}, \hat{\eta} \in \mathbb{R}^3\) are arbitrary constant vectors.

The mappings in (4.21) are called infinitesimal conformal mappings \(\phi_c\) (see [104]). The mappings \(x \to \phi_c(x)\) locally preserve the shape of infinitesimal cubes but are globally inhomogeneous.

![Figure 2: Infinitesimal conformal mappings \(\phi_c : \mathbb{R}^3 \to \mathbb{R}^3\) which locally leave shapes invariant: a prototype elastic deformation in the sense that the corresponding stress deviator \(\text{dev} \sigma(\nabla \phi_c) = 0.\) Shown is the coarse grid deformation. The picture is extracted from [104].](image)

If we consider \(x \to \phi_c(x)\) as elastic displacement, then, according to the von Mises \(J_2\)-criterion, these mappings alone never lead to plasticity since
\[ \text{dev} \sigma = \text{dev}(2 \mu \text{sym} \nabla \phi_c + \lambda \text{tr}(\nabla \phi_c \cdot 1)) = 2 \mu \text{dev sym} \nabla \phi_c = 0. \]

Gathering our findings, we have obtained that the regularization term (4.12) is invariant w.r.t. the infinitesimal conformal group and infinitesimal conformal mappings \(\phi_c\) do not induce irreversible processes.
There is still another solution to

$$\text{sym Curl sym } \nabla \vartheta = 0.$$  \hfill (4.22)

Clearly, (4.22) will be satisfied also if already

$$\text{Curl sym } \nabla \vartheta = 0,$$

which in turn is satisfied for

$$\text{sym } \nabla \vartheta = \nabla v \in \text{Sym}(3), \quad \text{with } v : \mathbb{R}^3 \to \mathbb{R}.$$  \hfill (4.23)

Such a vector can be taken as

$$v = \nabla h(x_1, x_2, x_3)$$

with any scalar function $h : \mathbb{R}^3 \to \mathbb{R}$. Then, (4.22) is satisfied. Thus, another solution to (4.22) is given by

$$\vartheta(x_1, x_2, x_3) = \nabla h(x_1, x_2, x_3), \quad h : \mathbb{R}^3 \to \mathbb{R}.$$

Altogether, solutions to (4.22) are represented by

$$\vartheta(x) = \frac{1}{2} \left( 2(\text{axl}(\widehat{W}), x) x - \text{axl}(\widehat{W}) \|x\|^2 \right) + [\widehat{\zeta} \cdot 1 + \widehat{A}] x + \widehat{\eta} + \nabla h(x),$$

as the new invariance group. We collect our finding in the following theorem.

**Theorem 4.1 [Nullspace of dev sym Curl sym Grad]**

The nullspace of the operator $\text{dev sym Curl sym Grad}$ is given by

$$\vartheta(x) = \frac{1}{2} \left( 2(\text{axl}(\widehat{W}), x) x - \text{axl}(\widehat{W}) \|x\|^2 \right) + [\widehat{\zeta} \cdot 1 + \widehat{A}] x + \widehat{\eta} + \nabla h(x),$$

where $\widehat{A}, \widehat{W} \in \mathfrak{so}(3)$ are arbitrary constant skew-symmetric matrices, $\widehat{\zeta}, \widehat{\eta} \in \mathbb{R}^3$ are arbitrary constant vectors and $h : \mathbb{R}^3 \to \mathbb{R}$ is any scalar function.

It is remarkable, that the seemingly similar regularization term $\|\text{Curl sym } \varepsilon_p\|^2 = \|\text{Curl } \varepsilon_p\|^2$ only allows for invariance under “potential” mappings $\vartheta = \nabla h$.

In order to be able to describe polygonization (see Figure 3(d)), the plasticity model should energetically favour configurations in which there are blocks of many homogeneous rotations. In this respect, the new term $\frac{1}{2} \mu L_c^2 \|\text{dev sym Curl sym } \varepsilon_p\|^2 = \frac{1}{2} \mu L_c^2 \|\text{sym Curl sym } \varepsilon_p\|^2$ energetically favours those configurations, which locally only rotate. The generated natural second order backstress will be of the type

$$\Sigma_{\text{curl}} = \mu L_c^2 \text{sym Curl (sym Curl } \varepsilon_p).$$

Now, looking at the invariance of the energy for which $\text{sym Curl (sym } \nabla \vartheta) = 0$ versus the invariance of the backstress in the strong formulation for which $\text{sym Curl (sym Curl (sym } \nabla \vartheta) = 0$, it is clear that the invariance of the energy implies the invariance of backstress, but not vice-versa.

**Remark 4.1** Note that the mapping $p \to \text{dev sym Curl sym } p = \text{sym Curl } \varepsilon_p$ does not have any geometric meaning connected to the incompatibility of the plastic distortion $p$ like Curl $p$ or connected to the incompatibility of the plastic strain tensor $\varepsilon_p = \text{sym } p$ like $\text{inc (sym } p)$. The simpler term Curl sym $p$ has been used by Gurtin and Anand [55] as the only energetic contribution in their irrotational gradient plasticity model.
Figure 3: Five states of a single crystal. (a) Unstrained. (b) Elastically bent. (c) Plastically bent. (d) Polygonized. (e) Recrystallized. The picture was extracted from Nabarro [93]. For the polygonized crystal, we observe large structures which are rotated against each other with a “zone” separating those blocks. Using plainly Curl $p$ as the underlying defect measure would energetically penalize these configurations. Therefore it seems appropriate to use inc(sym $p$) as a “weaker” defect measure which would allow for low energy configurations like that in (d).

4.3.3. Derivation of the modified model

Now with the additional term $W_{\text{curl}}(Dp) := \frac{1}{2} \mu L_c^2 \|\text{dev sym Curl} \varepsilon_p\|^{2} = \frac{1}{2} \mu L_c^2 \|\text{sym Curl} \varepsilon_p\|^{2}$ in the free-energy density $W$, if we repeat the derivation above starting from the free-energy imbalance, we get

$$0 \leq \int_{\Omega} \left[ \langle \sigma - \mu L_c^2 \text{sym Curl (sym Curl} \varepsilon_p) - \mu \tilde{L}_c^4 \text{inc}(\text{inc} \varepsilon_p), \dot{\varepsilon}_p \rangle - \mu k_2 \gamma_p \tilde{\gamma}_p \right] dx$$

$$- \sum_{i=1}^{3} \mu L_c^2 \int_{\partial\Omega} \langle \dot{\varepsilon}_{pi} \times n, (\text{sym Curl} \varepsilon_p)_{i} \rangle dS$$

$$- \sum_{i=1}^{3} \mu \tilde{L}_c^4 \int_{\partial\Omega} \langle \dot{\varepsilon}_{pi} \times n, [\text{Curl inc} \varepsilon_p]_{i}^{T} \rangle dS$$

$$- \sum_{i=1}^{3} \mu \tilde{L}_c^4 \int_{\partial\Omega} \langle [\text{Curl} \dot{\varepsilon_p}]_{i}^{T} \times n, [\text{inc} \varepsilon_p]_{i} \rangle dS$$

$$= \int_{\Omega} \left[ \langle \Sigma, \dot{\varepsilon}_p \rangle + g \tilde{\gamma}_p \right] dx - \sum_{i=1}^{3} \mu L_c^2 \int_{\partial\Omega} \langle \dot{\varepsilon}_{pi} \times n, (\text{sym Curl} \varepsilon_p)_{i} \rangle dS$$

$$- \sum_{i=1}^{3} \mu \tilde{L}_c^4 \int_{\partial\Omega} \langle [\text{Curl} \dot{\varepsilon_p}]_{i}^{T} \times n, [\text{inc} \varepsilon_p]_{i} \rangle dS$$

$$- \sum_{i=1}^{3} \mu \tilde{L}_c^4 \int_{\partial\Omega} \langle [\text{Curl inc} \varepsilon_p]_{i}^{T} \times n, [\text{inc} \varepsilon_p]_{i} \rangle dS$$

(4.23)
where
\[ \Sigma_E := \sigma + \Sigma_{\text{curl}} + \Sigma_{\text{inc}} \],
\[ g = -\mu k_2 \gamma_p, \]
\[ \Sigma_{\text{curl}} := -\mu L_c^2 \text{sym Curl}(\text{sym Curl } \varepsilon_p), \] (second order nonlocal backstress)
\[ \Sigma_{\text{inc}} := -\mu \hat{L}_c^4 \text{inc}(\text{inc } \varepsilon_p) \]
\[ = -\mu \hat{L}_c^4 \text{Curl} \left( \left[ \text{Curl Curl} \left[ \text{Curl } \varepsilon_p^T \right] \right]^T \right) \] (fourth order nonlocal backstress).

Now assuming again the simplest lower order boundary conditions
\[ \varepsilon_p \times n|_{\partial \Omega} = 0 \] and \[ \left[ \text{Curl } \varepsilon_p \right]^T \times n|_{\partial \Omega} = 0 \]
which will be clearly defined as Sobolev traces through a choice of a suitable function space for the plastic strain variable \( \varepsilon_p \), will guarantee the insulation type conditions
\[ \sum_{i=1}^{3} \int_{\partial \Omega} \langle \dot{\varepsilon}_{pi} \times n, (\text{sym Curl } \varepsilon_p^p) \rangle dS = 0, \] (4.26)
\[ \sum_{i=1}^{3} \int_{\partial \Omega} \langle \dot{\varepsilon}_{pi} \times n, \left[ \text{Curl inc } \varepsilon_p \right]^T \rangle dS = 0, \] (4.27)
\[ \sum_{i=1}^{3} \int_{\partial \Omega} \langle \left[ \text{Curl } \dot{\varepsilon}_p \right]^T \times n, \left[ \text{inc } \varepsilon_p \right]^T \rangle da = 0, \] (4.28)
from which we obtain the global reduced dissipation inequality
\[ \int_{\Omega} \left[ (\Sigma_E, \dot{\varepsilon}_p) + g \dot{\gamma}_p \right] dx \geq 0. \] (4.29)

**The flow law:** We consider the set of admissible (elastic) generalized stresses
\[ \mathcal{E} := \{ (\Sigma_E, g) \mid \| \text{dev } \Sigma_E \| - \sigma_0 - g \leq 0, \ g \leq 0 \}, \] (4.30)
whose interior \( \text{Int}(\mathcal{E}) \) is the elastic domain while its boundary \( \partial \mathcal{E} \) is the yield surface. The constant \( \sigma_0 \) is the initial yield stress of the material. The flow law in its primal form reads as follows:
\[ (\Sigma_E, g) \in \partial \mathcal{D}(\dot{\varepsilon}_p, \dot{\gamma}_p) \] (4.31)
where
\[ \mathcal{D}(q, \beta) := \sup \{ (\Sigma_E, q) + g \beta \mid (\Sigma_E, g) \in \mathcal{E} \} \]
\[ = \sup \{ (\Sigma_E, q) + g \beta \mid \| \Sigma_E \| \leq \sigma_0 - g, \ g \leq 0 \} \]
\[ = \begin{cases} \sigma_0 \| q \| & \text{if } \| q \| \leq \beta, \\ \infty & \text{otherwise}. \end{cases} \] (4.32)
Here, \( \partial D(\dot{\Gamma}_p) \) denotes the subdifferential of the function \( D \) at \( \dot{\Gamma}_p \). That is,

\[
(\Sigma_E, g) \in \partial D(\dot{\Gamma}_p, \dot{\gamma}_p) \iff (\Sigma_E, q - \dot{\epsilon}_p) + g(\beta - \dot{\gamma}_p) \leq D(q, \beta) - D(\dot{\epsilon}_p, \dot{\gamma}_p) \quad \forall (q, \beta).
\]

(4.33)

Now using convex analysis, we get

\[
(\Sigma_E, g) \in \partial D(\dot{\epsilon}_p, \dot{\gamma}_p) \iff (\dot{\epsilon}_p, \dot{\gamma}_p) \in \partial I_E(\Sigma_E, g) = N_E(\Sigma_E, g),
\]

(4.34)

where \( I_E \) is the indicator function of the set \( E \) of admissible generalized stresses and \( N_E(\Sigma_E, g) \) is the normal cone of the set \( E \) at \((\Sigma_E, g)\).

The condition (4.34) is called the dual form of the flow law, which in the case of smoothness of the yield surface \( \partial E \) at \((\Sigma_E, g)\) gives for some scalar parameter \( \lambda \geq 0 \)

\[
\dot{\epsilon}_p = \lambda \frac{\text{dev } \Sigma_E}{\|\text{dev } \Sigma_E\|} \quad \text{and} \quad \dot{\gamma}_p = \lambda = \|\dot{\epsilon}_p\|
\]

(4.35)

together with the Karush-Kuhn-Tucker complementary conditions:

\[
\lambda \geq 0, \quad \phi(\Sigma_E, g) \leq 0 \quad \text{and} \quad \lambda \phi(\Sigma_E, g) = 0.
\]

Note that with this choice, the global dissipation inequality (4.29) is satisfied.

4.3.4. Mathematical strong formulation of the model

Taking into account the free energy density \( W \) in (4.4) together with the additional term in (4.12) and the constraint \( \|q\| \leq \beta \) in the definition of the dissipation function \( D \) in (4.32), the model is strongly formulated as follows: find

(i) the displacement \( u \in H^1(0, T; H^1_0(\Omega, \Gamma, \mathbb{R}^3)) \),

(ii) the infinitesimal plastic strain \( \epsilon_p \in H^1(0, T; L^2(\Omega, \mathfrak{s}(3) \cap \text{Sym}(3))) \) with

\[
\text{sym Curl } \epsilon_p \in H^1(0, T; L^2(\Omega, \text{Sym}(3) \cap \mathfrak{s}(3))),
\]

\[
\text{inc } \epsilon_p = \text{Curl}[(\text{Curl } \epsilon_p)^T] \in H^1(0, T; L^2(\Omega, \mathbb{R}^{3 \times 3}))
\]

\[
\text{inc inc } \epsilon_p = \text{Curl}\left(\text{Curl Curl}[(\text{Curl } \epsilon_p)^T]^T\right) \in H^1(0, T; L^2(\Omega, \mathbb{R}^{3 \times 3})),
\]

(iii) The internal isotropic hardening variable \( \gamma_p \in H^1(0, T; L^2(\Omega)) \),

such that the content of Table 9 holds.

4.3.5. Weak formulation of the model

To obtain the weak formulation of the model, we consider the equilibrium in its weak formulation. That is, for every \( v \in H^1_0(\Omega, \mathbb{R}^3) \) we have

\[
\int_\Omega \langle C_{\text{iso}}(\text{sym } \nabla u - \epsilon_p), \text{sym}(\nabla v - \nabla \dot{u}) \rangle dx = \int_\Omega f(v - \dot{u}) dx.
\]

(4.36)

| Boundary conditions for \( \epsilon_p \): | \( \epsilon_p \times n|_{\partial \Omega} = 0, \quad (\text{Curl} \epsilon_p)^T \times n|_{\partial \Omega} = 0 \) |

Table 9: The new regularized irrotational model with isotropic hardening and Kröner’s incompatibility tensor. Also in this case, the boundary condition on \( \epsilon_p \) necessitates at least \( \epsilon_p, (\text{Curl} \epsilon_p)^T \in H(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \). The model is micro-random i.e., invariant w.r.t. \( p \rightarrow p + A(x), A(x) \in \mathfrak{so}(3) \) and invariant under infinitesimal conformal mappings \( p \rightarrow p + \nabla \phi_c \) with \( \text{dev} \nabla \phi_c = 0 \).

On the other hand, for every \( q \in C^\infty(\overline{\Omega}, \mathfrak{sl}(3) \cap \text{Sym}(3)) \) such that

\[
q \times n|_{\partial \Omega} = 0 \quad \text{and} \quad (\text{Curl} q)^T \times n|_{\partial \Omega} = 0
\]

and for every \( \beta \in L^2(\Omega) \), integrate (4.33) over \( \Omega \) using the pair of functions \((q, \beta)\) and get

\[
\int_{\Omega} \mathcal{D}(q, \beta) \, dx \geq \int_{\Omega} \mathcal{D}(\dot{\epsilon}_p, \dot{\gamma}_p) \, dx + \int_{\Omega} \left[ \langle \sigma + \Sigma_{\text{curl}} + \Sigma_{\text{inc}}, q - \dot{\epsilon}_p \rangle + g (\beta - \dot{\gamma}_p) \right] \, dx \tag{4.37}
\]

\[
= \int_{\Omega} \left[ \langle \sigma - \mu L^2_c \text{sym Curl} (\text{sym Curl} \epsilon_p) - \mu \hat{L}^4_c \text{inc} \epsilon_p, q - \dot{\epsilon}_p \rangle \right.
\]

\[
- \mu k_2 \gamma_p (\beta - \dot{\gamma}_p) \] \, dx.

Now integrating by parts the two terms \( \langle \text{sym Curl} (\text{sym Curl} \epsilon_p), q - \dot{\epsilon}_p \rangle \) once and \( \langle \text{inc} \epsilon_p, q - \dot{\epsilon}_p \rangle \) twice, using the boundary conditions

\[
(q - \dot{\epsilon}_p) \times n|_{\partial \Omega} = 0 \quad \text{and} \quad (\text{Curl}(q - \dot{\epsilon}_p))^T \times n|_{\partial \Omega} = 0
\]
we get from (4.37) that
\[
\int_{\Omega} D(q, \beta) \, dx \geq \int_{\Omega} D(\dot{\varepsilon}_p, \dot{\gamma}_p) \, dx + \int_{\Omega} \langle C_{iso}(\text{sym} \nabla u - \varepsilon_p), q - \dot{\varepsilon}_p \rangle \, dx \\
- \mu k_2 \int_{\Omega} \gamma_p (\beta - \dot{\gamma}_p) \, dx - \mu L_c^2 \int_{\Omega} \langle \text{sym} \nabla \varepsilon_p, \text{sym} \nabla (q - \dot{\varepsilon}_p) \rangle \, dx \\
- \mu \hat{L}_c^4 \int_{\Omega} \langle \text{inc} \varepsilon_p, \text{inc} (q - \dot{\varepsilon}_p) \rangle \, dx .
\] (4.38)

Adding (4.38) to the weak formulation of the equilibrium in (4.36), we get the weak formulation of our model of gradient plasticity with isotropic hardening and Kröner’s incompatibility tensor
\[
\int_{\Omega} \left[ \langle C_{iso}(\text{sym} \nabla u - \varepsilon_p), \text{sym} \nabla v - q \rangle - \mu k_2 \gamma_p (\beta - \dot{\gamma}_p) \\
+ \mu L_c^2 \langle \text{sym} \nabla \varepsilon_p, \text{sym} \nabla (q - \dot{\varepsilon}_p) \rangle + \mu \hat{L}_c^4 \langle \text{inc} \varepsilon_p, \text{inc} (q - \dot{\varepsilon}_p) \rangle \right] \, dx \\
+ \int_{\Omega} D(q, \beta) \, dx - \int_{\Omega} D(\dot{\varepsilon}_p, \dot{\gamma}_p) \, dx \geq \int_{\Omega} f(v - \dot{u}) \, dx .
\] (4.39)

That is,
\[
a(w, z - \dot{w}) + j(z) - j(\dot{w}) \geq \langle l, z - \dot{w} \rangle ,
\] (4.40)

where
\[
a(w, z) := \int_{\Omega} \left[ \langle C_{iso}(\text{sym} \nabla u - p), \text{sym} \nabla v - q \rangle + \mu k_2 \gamma_p \beta + \\
+ \mu L_c^2 \langle \text{sym} \nabla \varepsilon_p, \text{sym} \nabla q \rangle + \mu \hat{L}_c^4 \langle \text{inc} \varepsilon_p, \text{inc} q \rangle \right] \, dx ,
\] (4.41)
\[
j(z) := \int_{\Omega} D(q, \beta) \, dx ,
\] (4.42)
\[
\langle l, z \rangle := \int_{\Omega} f v \, dx ,
\] (4.43)
for \( w = (u, \varepsilon_p, \gamma_p) \) and \( z = (v, q, \beta) \).

4.3.6. Existence result for the weak formulation

We prove the existence result for the weak formulation (4.39) by closely following the approach by now classical, which uses the abstract machinery developed by Han and Reddy in [60] for mathematical problems in geometrically linear classical plasticity and used for instance in [33, 122, 99, 36, 40] for models of gradient plasticity. Precisely, we will need the following Theorem.

**Theorem 4.2 ([60, Theorem 6.19])**

Let \( Z \) be a Hilbert space and let \( W \) be a nonempty closed convex subset of \( Z \). Consider the following problem: find \( w \in H^1([0, T]; Z) \) with \( w(0) = 0 \) such that for almost every \( t \in [0, T] \), \( \dot{w}(t) \in W \) and
\[
a(\dot{w}, z - w) + j(z) - j(\dot{w}) \geq \langle l, z - \dot{w} \rangle \text{ for every } z \in W .
\] (4.44)

Assume that the following hold:
1. The bilinear form \( \mathbf{a} \) is symmetric, continuous on \( \mathbf{Z} \) and coercive on \( \mathbf{W} \), i.e., there exist \( C > 0 \) and \( \alpha > 0 \) such that
\[
\mathbf{a}(w, z) \leq C \|w\|_{\mathbf{Z}} \|z\|_{\mathbf{Z}} \quad \forall w, z \in \mathbf{Z} \quad \text{and} \quad \mathbf{a}(z, z) \geq \alpha \|z\|_{\mathbf{Z}}^2 \quad \forall z \in \mathbf{W};
\] (4.45)

2. The linear form \( \ell \) is bounded (written \( \ell \in \mathbf{Z}^* \) the dual space of \( \mathbf{Z} \)), i.e., there exists \( C > 0 \) such that
\[
|\ell(z)| \leq C \|z\|_{\mathbf{Z}} \quad \forall z \in \mathbf{Z};
\]

3. The functional \( j \) is non-negative, convex, positively 1-homogeneous and Lipschitz-continuous on \( \mathbf{W} \), i.e.,
\[
j(sz) = |s| j(z) \quad \forall s \in \mathbb{R}, \quad \forall z \in \mathbf{Z}
\]
\[
\exists L > 0 : |j(w) - j(z)| \leq L \|w - z\|_{\mathbf{Z}} \quad \forall w, z \in \mathbf{W}.
\] (4.46)

Then the problem (4.44) has a solution \( w \in H^1([0, T]; \mathbf{Z}) \).

Therefore, the problem is then reduced to finding a suitable Hilbert space \( \mathbf{Z} \) and its subset \( \mathbf{W} \) such that the bilinear form \( \mathbf{a}(\cdot, \cdot) \) and the functionals \( j \) and \( \ell \) satisfy the assumptions of Theorem 4.2.

The choices of function spaces for the displacement variable \( u \) and the isotropic hardening variable \( \gamma_p \) are straightforward as
\[
u \in H^1_0(\Omega; \mathbb{R}^3) \quad \text{and} \quad \gamma_p \in L^2(\Omega).
\]

For the plastic strain variable \( \varepsilon_p \), we first need to introduce the space
\[
\mathbf{H}_{\text{inc}}(\text{Curl}, \Omega; \mathfrak{sl}(3) \cap \text{Sym}(3)) := \{ q \in L^2(\Omega, \mathfrak{sl}(3) \cap \text{Sym}(3)) \mid (\text{Curl } q)^T \in \mathbf{H}(\text{Curl}, \Omega; \mathbb{R}^{3 \times 3}) \}
\]
\[
:= \{ q \in H(\Omega, \mathfrak{sl}(3) \cap \text{Sym}(3)) \mid \text{inc } q \in L^2(\text{Curl}, \Omega; \mathbb{R}^{3 \times 3}) \} \quad \text{(4.47)}
\]
equipped with the norm
\[
\|q\|_{\text{inc}}^2 := \|q\|_{L^2(\Omega)}^2 + \|(\text{Curl } q)^T\|_{\mathbf{H}(\text{Curl}, \Omega)}^2 = \|q\|_{L^2}^2 + \|(\text{Curl } q)^T\|_{L^2}^2 + \|\text{Curl}(\text{Curl } q)^T\|_{L^2}^2
\]
\[
= \|q\|_{H(\text{Curl}, \Omega)}^2 + \|\text{inc } q\|_{L^2(\Omega)}^2. \quad \text{(4.48)}
\]

Let us mention that spaces of functions involving the inc-operator were already used in the literature and we refer the interested reader for instance to the papers [10, 11].

We also consider the closure \( \mathbf{H}_{\text{sym, inc}}(\text{Curl}, \Omega, \partial \Omega; \mathfrak{sl}(3) \cap \text{Sym}(3)) \) of the linear subspace
\[
\left\{ q \in C^\infty(\overline{\Omega}, \text{Sym}(3)) \mid \text{tr } q = 0, \ q \times n|_{\partial \Omega} = 0 \quad \text{and} \quad (\text{Curl } q)^T \times n|_{\partial \Omega} = 0 \right\}
\]
in the norm
\[
\|q\|_{\text{sym curl, inc}}^2 := \|q\|_{L^2(\Omega)}^2 + \|\text{sym curl } q\|_{L^2}^2 + \|\text{inc } q\|_{L^2}^2. \quad \text{(4.49)}
\]
Motivated by the well-posedness question for models of infinitesimal gradient plasticity (specially for models dictated by invariance under infinitesimal rotations) [114, 115, 36, 113, 99], infinitesimal Cosserat elasticity [104, 64, 95], infinitesimal Cosserat elasto-plasticity [98, 107, 25, 100] and infinitesimal relaxed micromorphic [103, 106, 96], Bauer et al. [19, 20] (see also Neff et al. [109, 110, 111, 112])
derived a new inequality extending Korn’s first inequality to incompatible tensor fields, namely there exists a constant $C(\Omega) > 0$ such that

$$\forall X \in H(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}), \quad X \times n|_{\partial \Omega} = 0 : \quad \|X\|_{L^2(\Omega)} \leq C(\Omega) \left( \|\text{sym} X\|_{L^2(\Omega)} + \|\text{Curl} X\|_{L^2(\Omega)} \right).$$

(4.50)

Now, if we apply the incompatible Korn’s type inequality to $X = (\text{Curl} q)^T$ for $q \in C^\infty(\overline{\Omega}, \text{Sym}(3))$ with $(\text{Curl} q)^T \times n|_{\partial \Omega} = 0$, we get

$$\|\text{Curl} q\|_{L^2(\Omega)} \leq C(\Omega) \left( \|\text{sym}(\text{Curl} q)^T\|_{L^2(\Omega)} + \|\text{Curl} q\|_{L^2(\Omega)} \right)$$

(4.51)

then we have the decisive identity

$$H_{\text{sym}, \text{inc}} (\text{Curl}, \Omega, \partial \Omega; \mathfrak{s}l(3) \cap \text{Sym}(3))$$

$$\equiv \{ q \in H_0^1(\text{Curl}, \Omega, \partial \Omega; \mathfrak{s}l(3) \cap \text{Sym}(3)), \quad (\text{Curl} q)^T \in H_0(\text{Curl}, \Omega, \partial \Omega; \mathbb{R}^{3 \times 3}) \}$$

(4.52)

$$= \{ q, (\text{Curl} q)^T \in H(\text{Curl}, \Omega, \mathbb{R}^{3 \times 3}), \quad \text{tr} q = 0 \text{ a.e. in } \Omega, \quad q \times n|_{\partial \Omega} = (\text{Curl} q)^T \times n|_{\partial \Omega} = 0 \}$$

with the norms $\|\cdot\|_{\text{inc}}$ and $\|\cdot\|_{\text{symcurl}, \text{inc}}$ being equivalent.

Now, we set

$$V : = H^1_0(\Omega; \mathbb{R}^3),$$

(4.53)

$$Q : = \{ q \in H_0^1(\text{Curl}, \Omega; \mathfrak{s}l(3) \cap \text{Sym}(3)) \mid q \times n|_{\partial \Omega} = 0 \text{ and } (\text{Curl} q)^T \times n|_{\partial \Omega} = 0 \},$$

(4.54)

$$\Lambda : = L^2(\Omega),$$

(4.55)

$$Z : = V \times Q \times \Lambda,$$

(4.56)

$$W : = \{ z = (v, q, \beta) \in Z \mid \|q\| \leq \beta \},$$

(4.57)

equipped with the norms

$$\|v\|_V := \|\nabla v\|_{L^2(\Omega)}, \quad \|q\|_Q := \|q\|_{\text{inc}}, \quad \|\beta\|_\Lambda = \|\beta\|_{L^2(\Omega)},$$

$$\|z\|_Z^2 := \|v\|_V^2 + \|q\|_Q^2 + \|\beta\|_\Lambda^2$$

for $z = (v, q, \beta) \in Z$.

(4.58)

Let us prove the coercivity of the bilinear form $a(\cdot, \cdot)$ on the closed convex set $W$, where the constraint
\[ \|q\| \leq \beta \text{ in } W \text{ plays a crucial role. Let therefore } z = (v, q, \beta) \in W. \text{ Then,} \]

\[ a(z, z) \geq m_0 \|\text{sym}(\nabla v) - q\|^2_2 + \mu k_2 \|\beta\|^2_2 + \mu L^2_\text{c} \|\text{sym Curl } q\|^2_2 + \mu \hat{L}^4_\text{c} \|\text{inc } q\|^2_2 \]

\[ = m_0 \left[ \|\text{sym}(\nabla v)\|^2_2 + \|q\|^2_2 \right] - 2 \langle \text{sym}(\nabla v), p \rangle + \mu k \|\beta\|^2_2 + \mu L^2_\text{c} \|\text{sym Curl } q\|^2_2 + \mu \hat{L}^4_\text{c} \|\text{inc } q\|^2_2 \]

\[ \geq m_0 \left[ \|\text{sym}(\nabla v)\|^2_2 + \|q\|^2_2 - \theta \|\text{sym}(\nabla v)\|^2_2 - \frac{1}{\theta} \|q\|^2_2 \right] + \frac{1}{2} \mu k_2 \|\beta\|^2_2 \]

\[ + \frac{1}{2} \mu k_2 \|q\|^2_2 + \mu L^2_\text{c} \|\text{sym Curl } q\|^2_2 + \mu \hat{L}^4_\text{c} \|\text{inc } q\|^2_2 \]

\[ (\text{using Young’s inequality and } \|q\| \leq \beta \text{ from } W) \]

\[ = m_0 (1 - \theta) \|\text{sym}(\nabla v)\|^2_2 + \left[ m_0 (1 - \frac{1}{\theta}) + \frac{1}{2} \mu k_2 \right] \|q\|^2_2 + \frac{1}{2} \mu k_2 \|\beta\|^2_2 \]

\[ + \mu L^2_\text{c} \|\text{sym Curl } q\|^2_2 + \mu \hat{L}^4_\text{c} \|\text{inc } q\|^2_2. \]

So, choosing \( \theta \) such that \( \frac{2 m_0}{2 m_0 + \mu k_2} \leq \theta < 1 \), and using the classical Korn’s first inequality, there exists some positive constant \( K(m_0, \mu, k_2, \Omega) > 0 \) such that

\[ a(z, z) \geq K \left[ \|v\|^2_2 + \|q\|^2_2 + \|\beta\|^2_2 + \mu L^2_\text{c} \|\text{sym Curl } q\|^2_2 + \mu \hat{L}^4_\text{c} \|\text{inc } q\|^2_2 \right] \]

\[ \geq C \left[ \|v\|^2_2 + \|q\|^2_2 + \|\beta\|^2_2 \right] = C \|z\|^2_2 \quad \forall z = (v, q, \beta) \in W, \]

where \( C = C(m_0, \mu, k_2, \Omega, L_\text{c}, \hat{L}_\text{c}) > 0 \). For the second inequality in (4.59), we used the inequality (4.51) obtained as a consequence of Korn’s type inequality for incompatible tensor fields in Neff et al. \[109, 110, 111, 112]\).

So, assuming that the body is initially unloaded and undeformed, which corresponds to assuming that \( f(x, 0) = 0 \) for almost all \( x \in \Omega \) with homogeneous initial conditions, we obtained the following existence result for the weak formulation (4.39) of our model.

**Theorem 4.3** Under the choices of the Hilbert space \( Z \) and the closed convex subset \( W \) in (4.53)-(4.57) with the norms in (4.58) and the functionals \( a, j \) and \( \ell \) in (4.41)-(4.43), the weak formulation (4.39) when written as the variational inequality of the second kind (4.44) has a solution \( w = (u, \varepsilon_p, \gamma_p) \) in \( H^1([0, T]; Z) \) with \( \hat{w} \in L^2([0, T]; W) \).

**Remark 4.2** Uniqueness of the strong solution is obtained as in [39] provided the following further assumptions are satisfied:

\[ \text{sym Curl}(\text{sym Curl } \varepsilon_p) \in L^2(\Omega, \text{Sym}(3) \cap \mathfrak{sl}(3)) \quad \text{(4.60)} \]

\[ \text{Curl} \left( [\text{Curl Curl} [\text{Curl } \varepsilon_p]^T]^T \right) \in L^2(\Omega, \mathbb{R}^{3 \times 3}). \]
5. Discussion

It remains a difficult task to reconcile mathematical and physical requirements. Indeed, the incorporation of Kröner’s incompatibility tensor \( \varepsilon_p \) is physically transparent and the novel model is micro-random and gauge-invariant. Micro-randomness being useful for polycrystals and gauge-invariance being a generally physically necessary requirement. However, using integration by parts in order to arrive at a global reduced dissipation inequality, the following lowest order boundary conditions

\[
\varepsilon_p \times n|_{\partial \Omega} = 0 \quad \text{and} \quad (\text{Curl } \varepsilon_p)^T \times n|_{\partial \Omega} = 0
\]

impose themselves.

From a mathematical point of view these expressions are, however, not well-defined as boundary traces through a control of the given free-energy. In order to give them a well-defined meaning, we resorted to adding an additional term in the free-energy, namely

\[
\frac{1}{2} \mu L_c^2 \| \text{dev sym(Curl } \varepsilon_p)^T \|^2 = \frac{1}{2} \mu L_c^2 \| \text{sym(Curl } \varepsilon_p)^T \|^2.
\]

This term provides the missing boundary control for (5.1) by Korn’s-type inequality for incompatible tensor fields in Neff et al. \([109, 110, 111, 112, 19, 20]\). However, the additional term breaks the gauge-invariance of the model, while it satisfies the micro-randomness condition.

On the positive side, the invariance under the diffeomorphism group (gauge-invariance) is replaced by the invariance under infinitesimal conformal group (both statements adapted to our geometrically linear setting).

At the moment, we do not know how to set up a theory which is fully gauge-invariant and micro-random, while at the same time being mathematically well-posed. Consider e.g. a model with plastic spin and add \( \frac{1}{2} \mu L_c^2 \| \text{Curl } p \|^2 \) (see Table 6). This choice does not provide any control of \( \| \text{Curl sym } p \|^2 = \| \text{Curl } \varepsilon_p \|^2 \) necessary for well-posedness of (5.1).

A preliminary conclusion could be that the micro-randomness assumption, which effectively reduces the flow law to the six-dimensional space of symmetric plastic strains \( \varepsilon_p \), is to be critically seen in gradient plasticity approaches which are also supposed to satisfy gauge-invariance.

Acknowledgements:

We thank David J. Steigmann (University of Berkeley) for inspiring discussions on invariance conditions in plasticity theory which motivated us to introduce our micro-randomness condition and to consider the fourth order gradient plasticity model for polycrystals. The first author thanks the Faculty of Mathematics of the University of Duisburg-Essen (Germany) for its kind hospitality during his visit in April 2017.

Appendix

Let us first establish that

\[
\text{tr Curl } S = 0 \quad \forall S : \mathbb{R}^3 \to \text{Sym}(3) \text{ smooth tensor field.}
\]

(5.2)
In fact, recalling that $\text{Curl}(S)_{ij} = \sum_{kl=1}^{3} \epsilon_{ikl} S_{jl,k}$ we have

$$\text{tr}(\text{Curl } S) = \sum_{i} (\text{Curl } S)_{ii} = \sum_{i} \sum_{kl} \epsilon_{ikl} S_{jl,k}$$

$$= (S_{13,2} - S_{12,3}) + (S_{21,3} - S_{23,1}) + (S_{32,1} - S_{31,2}) = 0,$$

because $S \in \text{Sym}(3)$ and hence, $S_{13,2} = S_{32,1}, S_{12,3} = S_{23,1}$ and $S_{23,1} = S_{32,1}$.

Below are some further properties of the Kröner’s incompatibility tensor defined by

$$\text{inc}(\varepsilon_{p}) := \text{Curl}[(\text{Curl } \varepsilon_{p})^T].$$

For the convenience of the reader, we note that

$$\text{inc}(\varepsilon_{p}) \in \text{Sym}(3) \text{ since } \varepsilon_{p} \in \text{Sym}(3);$$

$$\text{inc}(\text{inc}(\varepsilon_{p})) \in \text{Sym}(3);$$

$$\text{tr}(\text{inc}(\varepsilon_{p})) = \Delta \text{tr}(\varepsilon_{p}) - \text{div}(\text{Div } \varepsilon_{p}) = - \text{div}(\text{Div } \varepsilon_{p}) \text{ since } \varepsilon_{p} \in \mathfrak{sI}(3);$$

$$\text{tr}(\text{inc}(\varepsilon_{p})) = - \Delta \text{div}(\text{Div } \varepsilon_{p}).$$

Since (5.6) follows from (5.5), let us establish here the identities (5.5)-(5.8) for the reader’s convenience. First of all, in components

$$(\text{Curl } \varepsilon_{p})_{ij} := \epsilon_{jkl} (\varepsilon_{p})_{il,k} \Leftrightarrow (\text{Curl } \varepsilon_{p})_{ij}^T := \epsilon_{ikl} (\varepsilon_{p})_{jl,k}.$$ 

Hence

$$(\text{inc } \varepsilon_{p})_{ij} = \text{Curl}[(\text{Curl } \varepsilon_{p})^T]_{ij} = \epsilon_{jkl} (\text{Curl } \varepsilon_{p})_{il,k}^T = \epsilon_{jkl} \epsilon_{imn} (\varepsilon_{p})_{ln,mk}.$$

Now, notice that $(\varepsilon_{p})_{ln,mk} = (\varepsilon_{p})_{nl,km}$. Therefore,

$$(\text{inc } \varepsilon_{p})_{ij} = \epsilon_{jkl} \epsilon_{imn} (\varepsilon_{p})_{ln,mk} = \epsilon_{imn} \epsilon_{jkl} (\varepsilon_{p})_{ln,mk} = \epsilon_{jln} \epsilon_{km} (\varepsilon_{p})_{ln,mk} = (\text{inc}(\varepsilon_{p}))_{ji},$$

which establishes (5.5). Now,

$$\text{tr}(\text{inc}(\varepsilon_{p})) = (\text{inc}(\varepsilon_{p}))_{ii} = \epsilon_{ikl} \epsilon_{imn} (\varepsilon_{p})_{ln,mk}.$$ 

Using the identity

$$\epsilon_{ikl} \epsilon_{imn} = \delta_{km} \delta_{ln} - \delta_{kn} \delta_{lm} \text{ (see for instance, [58, epsilon-delta identity (1.20)])},$$

we get

$$\text{tr}(\text{inc}(\varepsilon_{p})) = \delta_{km} \delta_{ln} (\varepsilon_{p})_{ln,mk} - \delta_{kn} \delta_{lm} (\varepsilon_{p})_{ln,mk} = (\varepsilon_{p})_{ll,mm} - (\varepsilon_{p})_{lk,lk}$$

$$= (\varepsilon_{p})_{ll,mm} - (\varepsilon_{p})_{kl,kl} = \Delta \text{tr}(\varepsilon_{p}) - (\text{Div } \varepsilon_{p})_{k,k}$$

$$= \Delta \text{tr}(\varepsilon_{p}) - \text{div}(\text{Div } \varepsilon_{p}) = - \text{div}(\text{Div } \varepsilon_{p}),$$

which establishes (5.7). So, from (5.7), it follows that if $\varepsilon_{p}$ is a divergence-free tensor or $\text{Div } \varepsilon_{p}$ is a divergence-free vector field, then $\text{inc}(\varepsilon_{p})$ becomes trace-free, that is, $\text{inc}(\varepsilon_{p}) \in \mathfrak{sI}(3)$. Now, to establish (5.8), notice that

$$\text{Div } \text{Curl } X = 0 \quad \forall X \in C^2(\Omega, \mathbb{R}^{3 \times 3}).$$
This trivially follows from our definitions of Curl and Div of a second tensor field as row-wise operations. Hence, \( \text{Div}(\text{inc } \varepsilon_p) = 0 \). So, using (5.7), we find that

\[
\text{tr}(\text{inc}(\text{inc } \varepsilon_p)) = \Delta \text{tr}(\text{inc } \varepsilon_p) - \text{div}(\text{Div}(\text{inc } \varepsilon_p)) = \Delta^2(\text{tr} \varepsilon_p) - \Delta(\text{div} \text{Div} \varepsilon_p)
\]

\[
= -\Delta(\text{div} \text{Div} \varepsilon_p) = -\text{div} \text{Div} \Delta \varepsilon_p,
\]

where \( \Delta^2 = \Delta(\Delta) \) denotes the bi-Laplacian operator. Therefore, the tensor inc(inc \( \varepsilon_p \)) is trace-free if one of the conditions below satisfied:

(i) \( \varepsilon_p \) is a divergence-free tensor field;

(ii) \( \text{Div} \varepsilon_p \) is a divergence-free vector field;

(iii) \( \text{div} \text{Div} \varepsilon_p \) is an harmonic function;

(iv) \( \varepsilon_p \) is an harmonic tensor field;

(v) \( \Delta \varepsilon_p \) is a divergence-free tensor field;

(vi) \( \text{Div} \Delta \varepsilon_p \) is a divergence-free vector field.
