

HOMOLOGY OF ALGEBRAIC VARIETIES: AN INTRODUCTION TO RECENT RESULTS OF SUSLIN AND VOEVODSKY

MARC LEVINE

1. INTRODUCTION

The recent series of papers by Suslin, Voevodsky, Suslin-Voevodsky and Friedlander-Voevodsky: [49], [50], [51], [52], [53] and [20], has developed a remarkable new viewpoint in the study of algebraic cycles. A new “topology” defined by Voevodsky, the qfh-topology, relates algebraic cycles to certain representing sheaves for this topology, and thus allows a systematic application of the powerful methods of sheaf-theory in areas which heretofore have been approached by essentially algebro-geometric or homotopy theoretic means. We hope to give here, not a full overview, but rather a sample of these new techniques and the results they have made possible. We will concentrate on the applications to the mod- n theory, for which the most striking applications have as yet appeared.

2. HISTORICAL BACKGROUND

Let X be a CW-complex. The topological K_0 (see [2], [3]) of X , $K_0^{\text{top}}(X)$, is defined as an abelian group via generators and relations: the generators are the isomorphism classes $[E]$ of complex vector bundles $E \rightarrow X$, with relations given by *stable equivalence*:

$$[E] \equiv [E'] \iff E \oplus e^n \cong E' \oplus e^n \text{ for some } n,$$

where e^n is the trivial rank n bundle on X . For X a finite CW complex, this group is also given as the homotopy classes of maps of X to the classifying space $BGL_{\mathbb{C}}$ of the topological group

$$GL_{\mathbb{C}} := \varinjlim_N GL_{N, \mathbb{C}},$$

where $GL_{N, \mathbb{C}}$ is the topological group of invertible n by n matrices over \mathbb{C} . The higher topological K -theory of a finite CW-complex X can then be defined as the homotopy groups of a function space:

$$K_n^{\text{top}}(X) := \pi_n(\text{Hom}(X, BGL_{\mathbb{C}})).$$

The filtration of X via its k -skeleta, together with Bott periodicity:

$$K_n^{\text{top}}(X) \cong K_{n+2}^{\text{top}}(X),$$

Key words and phrases. motives, cycles.
research supported by the NSF

gives rise to the *Atiyah-Hirzebruch spectral sequence* relating singular cohomology and topological K -theory; this spectral sequence degenerates rationally, giving the isomorphisms

$$\begin{aligned} K_{\text{even}}^{\text{top}}(X) \otimes \mathbb{Q} &\cong \bigoplus_n H^{2n}(X, \mathbb{Q}) \\ K_{\text{odd}}^{\text{top}}(X) \otimes \mathbb{Q} &\cong \bigoplus_n H^{2n+1}(X, \mathbb{Q}). \end{aligned}$$

The algebraic K_0 of an algebraic variety X is defined as the abelian group with generators the isomorphism classes $[E]$ of algebraic vector bundles E on X , with relations given by setting

$$[E] = [E'] + [E'']$$

if there exists an exact sequence

$$0 \rightarrow E' \rightarrow E \rightarrow E'' \rightarrow 0.$$

If X is affine, all such exact sequences split, and one gets the same group by imposing the relation of stable equivalence as in the topological case, but in general, stable equivalence is a weaker relation (they agree, however, in the topological setting). In fact, the algebraic K_0 was defined (by Grothendieck) *before* the topological case, but the higher K -theory in the topological setting was defined before the algebraic case.

Pursuing the analogy with the topological situation, Karoubi and Villamayor [31] gave a definition of higher algebraic K -theory of a ring R by means of the *discrete* group $\text{GL}(R)$, where the topology of $\text{GL}_{\mathbb{C}}$ is replaced by a certain simplicial structure. As this idea is central to our whole discussion, we give a description in a somewhat more general setting.

The algebraic version of homotopy is gotten by replacing the unit interval with the affine line \mathbb{A}^1 . Following this further, one considers the cosimplicial variety Δ^* , with n -cosimplices Δ^n given as the hyperplane in $n+1$ -space defined by the linear equation

$$\sum_{i=0}^n t_i = 1.$$

If one takes the t_i to be real numbers, with $0 \leq t_i \leq 1$, this is the usual n -simplex; as the usual expressions for the co-face and co-degeneracy maps between the n -simplex and the $n-1$ -simplex are linear functions of the t_i , one obtains the structure of a cosimplicial variety on Δ^* by using the same formulas as in the real case.

Starting with the map

$$\begin{aligned} \mathbb{A}^1 \times \mathbb{A}^1 &\rightarrow \mathbb{A}^1 \\ (s, t) &\mapsto st \end{aligned}$$

one can construct a map

$$(2.1) \quad H: \mathbb{A}^1 \times \Delta^* \rightarrow (\mathbb{A}^1 \times \Delta^*)^{[0,1]},$$

having the formal properties of a “homotopy” between the identity map on $\mathbb{A}^1 \times \Delta^*$ and the map

$$(x, t) \mapsto (0, t).$$

Now, suppose we have a functor (here **Sch** is the category of schemes)

$$F: \mathbf{Sch}^{\text{op}} \rightarrow \mathbf{Sets}$$

We may form the new functor

$$(2.2) \quad F_h: \mathbf{Sch}^{\text{op}} \rightarrow \mathbf{Simplicial\ Sets}$$

by

$$F_h(X) = F(X \times \Delta^*).$$

The simplicial set $F_h(X)$ then satisfies the *homotopy property*: by applying F to (2.1), one shows that the natural map

$$F_h(X) \rightarrow F_h(X \times \mathbb{A}^1)$$

is a homotopy equivalence on the geometric realization. Similarly, if we have a functor

$$F: \mathbf{Sch}^{\text{op}} \rightarrow \mathbf{Ab}$$

we may form the new functor with values in chain complexes

$$(2.3) \quad F_{h\mathbb{Z}}: \mathbf{Sch}^{\text{op}} \rightarrow \mathbf{C}(\mathbf{Ab})$$

by taking the chain complex associated to the simplicial abelian group F_h . The functor $F_{h\mathbb{Z}}$ is also homotopy invariant: the natural map

$$F_{h\mathbb{Z}}(X) \rightarrow F_{h\mathbb{Z}}(X \times \mathbb{A}^1)$$

is a quasi-isomorphism.

Now back to Karoubi-Villamayor K -theory. Suppose X is an affine variety with ring of functions R . The group $\text{GL}_N(R)$ is the group of algebraic maps

$$X \rightarrow \text{GL}_N,$$

where GL_N is the open subscheme of affine N^2 space defined as the locus where the determinant function is non-zero. Replacing X with $X \times \Delta^*$ gives the simplicial ring $\Delta_*(R)$ with

$$\Delta_n(R) = R[t_0, \dots, t_n] / \left(\sum_i t_i - 1 \right)$$

$$\text{Spec } \Delta_*(R) = X \times \Delta^*;$$

and the simplicial group $\text{GL}_N(\Delta_*(R))$:

$$\text{GL}_N(\Delta_n(R)) = \text{Hom}_{\text{alg}}(X \times \Delta^n, \text{GL}_N).$$

One then takes the geometric realization $|\text{GL}_N(\Delta_*(R))|$ of this simplicial set, passes to the limit over N , $|\text{GL}(\Delta_*(R))|$, and defines the *Karoubi-Villamayor K -theory* of R by

$$KV_n(R) = \pi_{n-1}(|\text{GL}(\Delta_*(R))|).$$

One can extend this definition to an arbitrary scheme by a sheafification process.

Quillen gave another definition of higher algebraic K -theory, first for rings by using his plus-construction [38], then for arbitrary exact categories via his categorical Q -construction [39]; this definition gained wide acceptance as the “correct” one in the general setting. It turns out that, for a regular scheme X (the algebro-geometric

version of a manifold), the Karoubi-Villamayor K -theory agrees with the Quillen K -theory, although for singular schemes, the two definitions are not in general the same.

In contrast with the topological case, the algebraic version of singular cohomology, the so-called “motivic cohomology”, was not completely defined until some fifteen years after the definition of algebraic K -theory. The first step towards the full definition of motivic cohomology was, however, taken quite a bit earlier, arising in the 50’s with the construction of the Chow ring of algebraic cycles modulo rational equivalence (see e.g. [56], [45], [8], [9], [7], [12] and [25]). What emerged from these constructions was an algebraic homology-like theory built out of the free abelian group on the algebraic subvarieties of X , the *algebraic cycles on X* . Replacing the unit interval with the affine line as above leads to the relation of *rational equivalence*, an algebraic version of homology. More precisely, a cycle is *rationally equivalent to zero* if it is of the form

$$\mathrm{pr}_X(W \cdot (X \times 0) - W \cdot (X \times 1))$$

for W a cycle on $X \times \mathbb{A}^1$, where pr_X is the projection on X , and \cdot is the intersection product (one requires that W contains no component of the form $W_0 \times t$, so that the intersection product is defined). One then defines the *Chow group* of X as the group of algebraic cycles modulo rational equivalence.

For smooth quasi-projective varieties, this homology-like theory has a cohomological flavor as well: the intersection of subvarieties extends to the *intersection product* on the group of cycles mod rational equivalence, defining the *Chow ring*

$$\mathrm{CH}^*(X) := \bigoplus_q \mathrm{CH}^q(X),$$

with the grading by codimension. In addition, the Chow ring admits functorial pull-back maps

$$f^*: \mathrm{CH}^*(X) \rightarrow \mathrm{CH}^*(Y)$$

for arbitrary maps $f: Y \rightarrow X$ between smooth, quasi-projective varieties. Grothendieck’s theory of Chern classes with values in the Chow ring [25], together with the Grothendieck-Riemann-Roch theorem [7], gives the isomorphism

$$\sum_q c_q: K_0(X) \otimes \mathbb{Q} \cong \bigoplus_q \mathrm{CH}^q(X) \otimes \mathbb{Q}.$$

The major inadequacy of both the algebraic K_0 and the Chow ring is the lack of good *localization sequence*, relating the theory for X , an open subscheme U , and the closed complement $Z := X \setminus U$. Both theories have the beginning (or end, depending on your point of view) of such a sequence; Quillen’s uniform definition of the higher K -groups, together with his localization theorem (see [39]), filled this gap on the K -theory side, giving the long exact sequence

$$\dots \rightarrow K_p(Z) \rightarrow K_p(X) \rightarrow K_p(U) \rightarrow K_{p-1}(Z) \rightarrow \dots \rightarrow K_0(X) \rightarrow K_0(U) \rightarrow 0$$

(this is for X and Z smooth; there is a similar sequence in general).

The first successful definition of motivic cohomology was supplied by Bloch in 1985, with his construction of the *higher* Chow groups [4]. The idea is to make sense of the algebraic cycles on the co-simplicial variety $X \times \Delta^*$. The technical problem here is that an arbitrary codimension q subvariety of $X \times \Delta^p$ may not

intersect a face $X \times \Delta^{p'}$ in codimension q , and thus the intersection product with this face is not defined; Bloch solves this by considering the subgroup generated by subvarieties which *do* intersect all faces in the correct codimension. This gives the homological complex $\mathcal{Z}^q(X, *)$, with $\mathcal{Z}^q(X, p)$ being the subgroup of the cycles on $X \times \Delta^p$ just described, and differential given by the pull-back via the coboundary maps in $X \times \Delta^*$ (i.e., intersection with the codimension one faces $X \times \Delta^{p-1}$ of $X \times \Delta^p$). The higher Chow groups are then defined as the homology

$$\mathrm{CH}^q(X, p) := H_p(\mathcal{Z}^q(X, *))$$

This extends the definition of the Chow ring $\mathrm{CH}^q(X)$, via the identity

$$\mathrm{CH}^q(X) = \mathrm{CH}^q(X, 0).$$

It wasn't until around 1992 that the localization property for $\mathrm{CH}^q(X, *)$ was proved (see [5]), and this only for varieties over a field of characteristic 0. We do know, however (see e.g. [32]), that there is a close relation between the higher algebraic K -theory and the higher Chow groups of a variety X which is smooth over a field, so the higher Chow groups do seem to be the ‘‘correct’’ groups for motivic cohomology.

3. THE QUILLEN-LICHTENBAUM CONJECTURE.

Let X be a variety defined over \mathbb{C} , $X(\mathbb{C})$ the topological space of solutions to the equations defining X . Passing from algebraic maps to continuous maps defines the comparison map from algebraic to topological K -theory

$$K_p^{\mathrm{alg}}(X) \rightarrow K_p^{\mathrm{top}}(X(\mathbb{C})).$$

In general, this map is far from being an isomorphism. However, the situation seems to get quite a bit simpler if one takes K -theory with mod n coefficients (defined via mod n homotopy groups of the appropriate spaces):

$$K_p^{\mathrm{alg}}(X; \mathbb{Z}/n) \rightarrow K_p^{\mathrm{top}}(X(\mathbb{C}); \mathbb{Z}/n).$$

The so-called *Quillen-Lichtenbaum conjecture* asserts (in one of its forms) that this map is an isomorphism for $p \geq 2 \dim_{\mathbb{C}}(X)$.

One can extend this to varieties over more general fields as follows. Grothendieck *et al.* [26] have defined the *étale cohomology*, $H_{\mathrm{ét}}^p(X, \mathbb{Z}/n)$, of a scheme X , which (for n invertible on X) has many of the formal properties of the mod n singular cohomology of a space (see §5 for more information). In fact, the *comparison theorem* of Artin gives a natural isomorphism between the étale cohomology $H_{\mathrm{ét}}^p(X, \mathbb{Z}/n)$ of a scheme X defined over \mathbb{C} , and the singular cohomology $H^p(X(\mathbb{C}), \mathbb{Z}/n)$ of the analytic space of solutions $X(\mathbb{C})$. Building on the methods of Grothendieck, Friedlander [14], [15], and Dwyer-Friedlander [13] constructed an algebro-geometric version of mod n topological K -theory, the *étale K -theory* $K_*^{\mathrm{ét}}(X; \mathbb{Z}/n)$. There is an Atiyah-Hirzebruch spectral sequence in the étale case as well, relating $H_{\mathrm{ét}}^*(X, \mathbb{Z}/n)$ and $K_*^{\mathrm{ét}}(X; \mathbb{Z}/n)$.

The Quillen-Lichtenbaum conjecture then asserts that the natural map of mod- n algebraic K -theory to mod- n étale K -theory of a variety X over a field k :

$$K_p^{\mathrm{alg}}(X; \mathbb{Z}/n) \rightarrow K_p^{\mathrm{ét}}(X; \mathbb{Z}/n)$$

is an isomorphism for $p \geq 2\dim_k(X) + \text{c.d.}(k)$, where $\text{c.d.}(k)$ the mod n cohomological dimension of the Galois group of \bar{k}/k . Via the theory of Chern classes to étale cohomology, this can be interpreted as stating that the Chern class maps induce isomorphisms (for F a field)

$$\sum_{2q-p=m} c_{q,p}: K_m(F; \mathbb{Z}/n) \rightarrow \oplus_{2q-p=m} H_{\text{ét}}^p(F, \mathbb{Z}/n(q)); \quad 2q \geq p,$$

for n prime to “small primes” (depending on m) and prime to the characteristic of F .

We should mention here that the original conjecture of Quillen and Lichtenbaum (see e.g. [34]) concerned itself only with the K -groups and étale cohomology of *number rings*, and that the conjecture stated above is a slight modification of Conjecture 3.9 in [15].

Thus, one hopes for natural isomorphisms,

$$(3.1) \quad H_{\mu}^p(X, \mathbb{Z}/n(q)) \rightarrow H_{\text{ét}}^p(X, \mathbb{Z}/n(q)); \quad 2q \geq p, \quad q \geq \dim_k(X),$$

where $H_{\mu}^p(X, \mathbb{Z}/n(q))$ is the mod- n motivic cohomology of a smooth k -scheme X ; at least provisionally, this can be defined via Bloch’s cycle complex as

$$H_{\mu}^p(X, \mathbb{Z}/n(q)) = H_{2q-p}(\mathcal{Z}^q(X, *) \otimes \mathbb{Z}/n).$$

One main result of Suslin and Voevodsky ([49] and [48]) is that, for varieties over an algebraically closed field, such isomorphisms exist.

In fact, the major player in the proof is not Bloch’s cycle complex, but a homological version introduced by Suslin (in a 1988 lecture at Luminy). The *Suslin homology* of a scheme X is defined in terms of families of zero cycles on X , parametrized by the co-simplicial scheme Δ^* . There was no serious progress in the study or application of Suslin homology until Voevodsky introduced his qfh-topology and h-topology in 1992; this provided the needed breakthrough by allowing an interpretation of the mod n Suslin cohomology (the dual of Suslin homology) as a cohomology theory arising from sheaves on a Grothendieck site.

4. RELATIVE 0-CYCLES AND SUSLIN HOMOLOGY OF SCHEMES

A pointed topological space $(X, *)$ freely generates a commutative monoid with $*$ acting as identity, the *pointed infinite symmetric product* $Sp^{\infty}X$, whose points are the finite formal sums $\sum_i x_i$ with $x_i \in X$, modulo the relation

$$n \cdot * + \sum_i x_i \sim \sum_i x_i.$$

If $(X, *)$ is a connected CW complex, the theorem of Dold and Thom [11] shows that $Sp^{\infty}X$ represents the homology of X , via a natural isomorphism

$$\pi_n(Sp^{\infty}X) \cong H_n(X; \mathbb{Z}).$$

One can mimick this in the algebraic setting. Rather than attempting to deal with the infinite dimensional scheme $Sp^{\infty}X$, Suslin considers a functor which is in principle the one represented by the group completion of $Sp^{\infty}X$. As in §2, one replaces the topology on $Sp^{\infty}X$ induced by that of X with the simplicial structure induced by Δ^* .

DEFINITION 4.1. Let X and S be k -schemes, with S smooth and irreducible. Define the group $C_0(S; X)$ to be the free abelian group on the subvarieties W of $X \times S$ such that the projection $p_2: W \rightarrow S$ is finite and surjective (recall that a map $f: Y \rightarrow Z$ is finite if f is proper and each fiber of f is a finite set). Set

$$C_n(S; X) = C_0(S \times \Delta^n; X).$$

The group $C_0(S; X)$ is covariantly functorial in X and contravariant in S ; thus, we may form the complex (see (2.2))

$$C_*(S; X) := C_0(S \times \Delta^*; X) = C_0(S; X)_{h\mathbb{Z}};$$

and the homology

$$H_p^{\text{sing}}(S; X) := H_p(C_*(S; X)).$$

The groups $H_p^{\text{sing}}(S; X)$ are thus covariant in X and contravariant in S .

EXAMPLE 4.2. Take $S = \text{Spec } k$. Then $H_p^{\text{sing}}(k; X)$ is the *Suslin homology* of X . Sending X to $H_p^{\text{sing}}(X; \mathbb{Z}) := H_p^{\text{sing}}(k; X)$ defines the functor

$$H_p^{\text{sing}}(-; \mathbb{Z}): \mathbf{Sch}/k \rightarrow \mathbf{Ab}$$

Let Y be a smooth irreducible k -scheme, and define $C_0(X)(Y)$ by

$$(4.1) \quad C_0(X)(Y) := C_0(Y; X).$$

This defines the (contravariant) functor $C_0(X)$ on the category \mathbf{Sm}/k of smooth, finite-type k -schemes.

5. GROTHENDIECK TOPOLOGIES

Grothendieck topologies play a central role in the arguments of Suslin-Voevodsky; we give here a brief overview. For more details see, e.g., [1], [35], [10], and [26].

Grothendieck introduced the notion of a Grothendieck topology, and the associated category of sheaves for the topology, in the construction of étale cohomology, the algebro-geometric replacement of singular cohomology. To form a topology on a set X , one selects a collection of subsets of X , the *open* subsets for the topology, subject to certain axioms. Grothendieck extended this notion by considering the inclusion of an open subset as a special case of a morphism in a category, and considering, for a category \mathcal{C} , families of morphisms in \mathcal{C}

$$f_\alpha: U_\alpha \rightarrow X,$$

satisfying axioms which generalize the notion of an open cover.

More specifically, for each object U of \mathcal{C} , one must define when a family of morphisms

$$\{U_\alpha \rightarrow U \mid \alpha \in A\}$$

in \mathcal{C} is a *cover* of U ; one requires

(1) *stability under base-change*: if

$$\{U_\alpha \rightarrow U \mid \alpha \in A\}$$

is a cover of U , and $V \rightarrow U$ is a morphism in \mathcal{C} , then the fiber product $U_\alpha \times_U V$ exists for each α , and the family

$$\{p_2: U_\alpha \times_U V \rightarrow V \mid \alpha \in A\}$$

is a cover of V ,

(2) *local determination*: if

$$\{U_\alpha \rightarrow U \mid \alpha \in A\}$$

is a cover of U , and if

$$\mathcal{V} := \{V_\beta \rightarrow U \mid \beta \in B\}$$

is a collection of morphisms in \mathcal{C} , such that

$$\{U_\alpha \times_U V_\beta \rightarrow U_\alpha \mid \beta \in B\}$$

is a cover of U_α for each α , then \mathcal{V} is a cover of U .

(3) *stability under composition*: if

$$\{U_\alpha \xrightarrow{f_\alpha} U \mid \alpha \in A\}$$

is a cover of U , and if

$$\{V_\beta \xrightarrow{g_{\alpha\beta}} U_\alpha \mid \beta \in B_\alpha\}$$

is a cover of U_α for each α , then

$$\{V_\beta \xrightarrow{f_\alpha \circ g_{\alpha\beta}} U \mid \beta \in B_\alpha, \alpha \in A\}$$

is a cover of U .

(4) each isomorphism

$$U' \rightarrow U$$

forms a cover of U .

As category together with a Grothendieck topology is called a *Grothendieck site*.

We have actually defined above the notion of a Grothendieck *pre-topology* on \mathcal{C} ; this suffices to define the primary objects of interest: presheaves and sheaves. A Grothendieck pre-topology generates a Grothendieck topology, just as a basis for a topology generates a topology, so we will freely confuse the two notions in what follows.

One can view a topology in the usual sense on a set X as a Grothendieck topology, by defining \mathcal{C} to be the category formed by the inclusion maps $V \rightarrow U$ among the open subsets of X , and defining the covers of $U \subset X$ to be collections

$$\{U_\alpha \rightarrow U\},$$

with

$$\cup_\alpha U_\alpha = U,$$

i.e., open covers of U .

Conversely, if one has a Grothendieck topology on a category \mathcal{C} , one can consider the morphisms

$$f: V \rightarrow U$$

which occur in some cover $\{f_\alpha: U_\alpha \rightarrow U\}$ as an “open subset” of U . If the category \mathcal{C} has a final object X , and if each morphism $V \rightarrow U$ occurs in some cover of U , then one may consider the Grothendieck topology on \mathcal{C} as a “Grothendieck topology on X ”, and the objects of \mathcal{C} as the opens for the Grothendieck topology.

In the general case, a Grothendieck topology \mathfrak{T} on a category \mathcal{C} induces the Grothendieck topology \mathfrak{T}_X on each object X of \mathcal{C} by forming the category \mathcal{C}_X of maps $U \rightarrow X$ which occur in a cover of X , where a map $(U \rightarrow X) \rightarrow (V \rightarrow X)$ is a commutative triangle

$$\begin{array}{ccc} U & \rightarrow & V \\ & \searrow & \swarrow \\ & X & \end{array}$$

and using the covers in \mathfrak{T} to define the covers in \mathfrak{T}_X . The operation of restricting to an object of \mathcal{C} is like taking the induced topology on a subset of a topological space. One can consider a Grothendieck topology on a category \mathcal{C} as being defined by giving a Grothendieck topology on X for each object X of \mathcal{C} , with this assignment being natural in X .

Once one has a Grothendieck topology \mathfrak{T} on a category \mathcal{C} , one defines a presheaf F (say of abelian groups) for the topology as a contravariant functor from \mathcal{C} to \mathbf{Ab} . A sheaf is a presheaf F that satisfies the sheaf axiom: if

$$\{i_\alpha: U_\alpha \rightarrow U\}$$

is a cover of U , then the sequence

$$0 \rightarrow F(V) \xrightarrow{\prod_\alpha F(i_\alpha)} \prod_\alpha F(U_\alpha) \xrightarrow[\prod_{\alpha,\beta} F(p_2)]{F(p_1)} \prod_{\alpha,\beta} F(U_\alpha \times_V U_\beta)$$

is exact. The category $\text{Sh}_{\mathfrak{T}}$ of sheaves of abelian groups for the topology \mathfrak{T} is then an abelian category, so one can perform the usual operations of homological algebra in this setting. If X is in \mathcal{C} , using the topology \mathfrak{T}_X on \mathcal{C}_X , one has the notions of a pre-sheaf or a sheaf on X , giving the category of sheaves on X for the topology \mathfrak{T} , $\text{Sh}_{\mathfrak{T}}(X)$.

There is also the operation of sheafifying a presheaf, so one has in particular the “constant” sheaf A_X on X for each abelian group A . As one has the canonical isomorphism

$$\text{Hom}_{\text{Sh}_{\mathfrak{T}}(X)}(\mathbb{Z}_X, \mathcal{F}) \cong \mathcal{F}(X),$$

the groups $\text{Ext}^p(\mathbb{Z}_X, \mathcal{F})$ are the higher derived functors of the global sections functor; one can therefore define the cohomology of a sheaf \mathcal{F} on X for the topology \mathfrak{T} by

$$(5.1) \quad H_{\mathfrak{T}}^p(X; \mathcal{F}) = \text{Ext}_{\text{Sh}_{\mathfrak{T}}(X)}^p(\mathbb{Z}_X, \mathcal{F}).$$

EXAMPLE 5.1.

- (1) The Zariski topology on a scheme X is a topology in the classical sense, with opens being complements of algebraic subsets F of X . One makes the Zariski topology into a Grothendieck topology as described above.

- (2) For X a smooth scheme of finite type over an algebraically closed field k , an étale map is a morphism $i: U \rightarrow X$ whose differential di_u is an isomorphism for all k points $u \in U$. For example, if X is a smooth variety over \mathbb{C} , and $f: Y \rightarrow X$ is *proper*, then f is étale if and only if the map of complex manifolds $f(\mathbb{C}): Y(\mathbb{C}) \rightarrow X(\mathbb{C})$ is a covering space (necessarily finite). More generally, if X is still over \mathbb{C} , but not necessarily smooth, then a map $f: Y \rightarrow X$ is étale if and only if, for each point y of Y , there are neighborhoods U of $y \in Y(\mathbb{C})$ and V of $f(y) \in X(\mathbb{C})$ (in the \mathbb{C} -topology) such that f gives an isomorphism

$$f(\mathbb{C}): U \rightarrow V.$$

We omit the general definition of an étale morphism.

The étale topology on a scheme X is given by taking the category of “opens of X ” to be the étale maps $U \rightarrow X$ (of finite type), and saying that a cover of $U \rightarrow X$ is a collection of étale maps

$$\{f_\alpha: U_\alpha \rightarrow U\}$$

such that

$$U = \cup_\alpha f_\alpha(U_\alpha).$$

Using the methods discussed above, one has the étale cohomology of a scheme X with coefficients in an étale sheaf \mathcal{F} , $H_{\text{ét}}^*(X, \mathcal{F})$.

REMARK 5.2. Let x be a point of a variety X . The *henselization* X_x^h of X at x plays the role, for the étale topology, of a small neighborhood of x in X in the classical topology. The henselization is gotten by taking the inverse limit over the the collection of pointed étale map

$$(Y, y) \rightarrow (X, x).$$

For instance, if the base field k is algebraically closed, and x is a smooth k -point of a smooth k -variety X of dimension d , then X_x^h is isomorphic to the henselization $(\mathbb{A}^d)_0^h$ of affine d -space at the origin.

The examples in 5.1 describe the so-called *small* site: giving a Grothendieck topology for a single scheme X ; giving a Grothendieck topology on the category \mathbf{Sch}/k of schemes over over a fixed base field k defines what is known as a *big* site.

For example, the étale topology on a scheme X is natural in X : if $U \rightarrow X$ is étale, and $f: Y \rightarrow X$ is a morphism of schemes, then $U \times_X Y \rightarrow Y$ is étale. This gives us the big étale site on \mathbf{Sch}/k . The big Zariski site is defined similarly.

Now, suppose we have a sheaf \mathcal{F} on \mathbf{Sch}/k for some topology \mathfrak{T} . For a k -scheme X , one can restrict \mathcal{F} to X to give the sheaf \mathcal{F}_X for the topology \mathfrak{T}_X , and the cohomology $H^*(X, \mathcal{F}_X)$, defined as in (5.1) as the Ext groups

$$H^*(X, \mathcal{F}_X) = \text{Ext}_{\text{Sh}_{\mathfrak{T}_X}(X)}^*(\mathbb{Z}_X, \mathcal{F}_X).$$

One can also define the cohomology on X entirely in the category $\text{Sh}_{\mathfrak{T}}/k$ of sheaves on \mathbf{Sch}/k in the following way: Let

$$\text{Hom}_k(-, X): \mathbf{Sch}/k^{\text{op}} \rightarrow \mathbf{Sets}$$

be the functor represented by X

$$Y \mapsto \mathrm{Hom}_k(Y, X).$$

Form the free abelian group on $\mathrm{Hom}_k(-, X)$, giving the presheaf

$$\mathbb{Z}[\mathrm{Hom}_k(-, X)]: \mathbf{Sch}/k^{\mathrm{op}} \rightarrow \mathbf{Ab}.$$

Let $\mathbb{Z}_{\mathfrak{T}}(X)$ denote the sheafification of $\mathbb{Z}[\mathrm{Hom}_k(-, X)]$ for the topology \mathfrak{T} . It follows from the Yoneda lemma that there is an natural isomorphism

$$(5.2) \quad H_{\mathfrak{T}, X}^*(X, \mathcal{F}_X) = \mathrm{Ext}_{\mathrm{Sh}_{\mathfrak{T}, X}(X)}^*(\mathbb{Z}_X, \mathcal{F}_X) \cong \mathrm{Ext}_{\mathrm{Sh}_{\mathfrak{T}}/k}^*(\mathbb{Z}_{\mathfrak{T}}(X), \mathcal{F}),$$

which is the interpretation of sheaf cohomology on X we wanted.

We shall see in the next section that two new topologies, both finer than the étale topology, provide via (5.2) the link between mod n étale cohomology and Suslin homology.

6. THE h-TOPOLOGY AND THE qfh-TOPOLOGY

Voevodsky's qfh-topology allows one to use the machinery of sheaf cohomology in the study of algebraic cycles; the h-topology is perhaps a more natural construction, but the resulting sheaf cohomology is not so obviously related to cycles. As we shall later see, the mod- n cohomologies in the h- and qfh-topologies agree, so the two points of view complement each other.

We fix a base field k , and write \mathbf{Sch}/k for the category of schemes of finite type over k .

DEFINITION 6.1.

- (1) Let $f: X \rightarrow Y$ be a map of k -schemes. f is a *topological epimorphism* if f is surjective on points and if Y has the quotient topology, i.e., a subset U of Y is open if and only if $f^{-1}(U)$ is open in X . f is a *universal topological epimorphism* if, for each map of schemes $Z \rightarrow Y$, the projection

$$Z \times_Y X \rightarrow Z$$

is a topological epimorphism.

- (2) The *h-topology* on \mathbf{Sch}/k is the Grothendieck topology for which an h-cover of Y is a universal topological epimorphism $X \rightarrow Y$.
- (3) the *qfh-topology* on \mathbf{Sch}/k is the Grothendieck topology for which a qfh-cover of Y is a universal topological epimorphism $X \rightarrow Y$ which is quasi-finite over Y (the inverse image of each point of Y is a finite set).

The following structure theorem gives a more concrete idea of the h-topology and qfh-topology.

Theorem 6.2. *i) Let $V \rightarrow Y$ be an h-cover. There is a refinement of V ,*

$$\begin{array}{ccc} U & \rightarrow & V \\ & \searrow & \swarrow \\ & Y & \end{array}$$

and a factorization of $U \rightarrow Y$ as

$$(6.1) \quad U = \coprod_i U_i \xrightarrow{j} X \xrightarrow{p} Z \xrightarrow{q} Y$$

where p is a finite morphism, q is the blow-up of a closed subscheme of Y , and j is a Zariski open cover. Conversely, each morphism $U \rightarrow Y$ which factors as in (6.1) is an h -cover.

ii) Let $V \rightarrow Y$ be a qfh -cover. There is a refinement of V ,

$$\begin{array}{ccc} U & \rightarrow & V \\ & \searrow & \swarrow \\ & Y & \end{array}$$

and a factorization of $U \rightarrow Y$ as

$$(6.2) \quad U = \coprod_i U_i \xrightarrow{j} X \xrightarrow{p} Y$$

where p is a finite morphism and j is a Zariski open cover. Conversely, each morphism $U \rightarrow Y$ which factors as in (6.2) is a qfh -cover.

REMARK 6.3. i) Clearly the h -topology is finer than the qfh -topology. The qfh -topology is finer than the étale topology.

ii) If the characteristic of k is zero, one may use Hironaka's resolution of singularities to show that each h cover of a k -scheme Y has a refinement $U \rightarrow Y$ with U smooth over k . In characteristic $p > 0$, the recent work of de Jong [29] gives the same result. This is certainly *not* the case for qfh -covers, even of a smooth k -scheme. This points out an important technical advantage of the h -topology over the qfh -topology: every k -scheme is locally smooth in the h -topology, while only 0 and 1-dimensional k -schemes are locally smooth in the qfh -topology.

7. FAMILIES OF 0-CYCLES AND THE qfh -TOPOLOGY

We have seen in (5.2) that the sheafification $\mathbb{Z}_{\mathfrak{f}}(X)$ of the abelian group generated by the representing presheaf $\text{Hom}(-, X)$ plays a central role in understanding sheaf cohomology. We have the “family of 0-cycles on X ” functor of example 4.1:

$$C_0(X): \mathbf{Sm}/k^{\text{op}} \rightarrow \mathbf{Ab}$$

The qfh -topology links sheaf cohomology with algebraic cycles via

Theorem 7.1. *Let p be the exponential characteristic of the base field k ($p = \text{char}(k)$ if $\text{char}(k) > 0$, $p = 1$ if $\text{char}(k) = 0$). The functor $C_0(X)[1/p]$ on \mathbf{Sm}/k extends uniquely to a qfh -sheaf (denoted $c_0(X)$) on \mathbf{Sch}/k . Moreover, $c_0(X)$ is naturally isomorphic to the “representing” qfh -sheaf $\mathbb{Z}_{qfh}(X)[1/p]$.*

The map relating $\mathbb{Z}_{qfh}(X)[1/p]$ and $C_0(X)[1/p]$ is gotten by sending a morphism

$$f: Y \rightarrow X$$

to the transpose of the graph in $X \times Y$. The proof of first part of theorem 7.1 can be divided into two steps: the first step consists in extending $C_0(X)[1/p]$ to normal schemes. This is accomplished in [48] by Galois-theoretic methods, and in [50] by a

type of limit process, reminiscent of the method of Weil [56] for defining intersection multiplicities. The extension from normal schemes to arbitrary schemes of finite type is then a fairly formal process, using the fact that a reduced scheme of finite type is a direct limit of normal schemes.

Another crucial property of qfh-sheaves is that they admit *transfers*. Recall that a map of schemes $f: X \rightarrow Y$ is *finite* if f is proper and quasi-finite ($f^{-1}(y)$ is a finite set for each $y \in Y$). For instance, a finite extension of field $K \rightarrow L$ defines a finite morphism $\text{Spec } L \rightarrow \text{Spec } K$. If P is a presheaf on \mathbf{Sch}/k , a transfer on P is gotten by giving a map

$$\text{Tr}_{X/S} = \text{Tr}_p: P(X) \rightarrow P(S),$$

for each finite morphism $p: X \rightarrow S$ with X and S reduced and irreducible, and S smooth. These maps should be compatible with pull-back in cartesian squares in a sense which we will leave vague. Now, in the qfh-topology, each finite map $X \rightarrow S$ is an open cover, and the sheaf axiom shows that, at least if $X \rightarrow S$ is Galois with group of automorphisms G , taking the trace

$$\begin{aligned} \text{Tr}: P(X) &\rightarrow P(X) \\ x &\mapsto \sum_{g \in G} x^g \end{aligned}$$

defines a map $P(X) \rightarrow P(S)$. The general case follows with a bit of additional work.

8. THE h-TOPOLOGY AND THE RIGIDITY THEOREM

As the h-topology is finer than the qfh-topology, an h-sheaf also has transfers. The crucial property of sheaves for the h-topology is expressed by the *rigidity theorem*.

The original precursor of the rigidity theorem may be found on Roitman's work on zero-cycles. The work [42] considers the torsion subgroup of the group of zero-cycles modulo rational equivalence on a smooth projective variety X over an algebraically closed field k , and the behavior of this group under the *Albanese mapping*:

$$\alpha_X: \text{CH}_0(X) \rightarrow \text{Alb}(X).$$

Here $\text{Alb}(X)$ is the Albanese variety of X , a finite dimensional projective algebraic group. Roitman [41], extending the work of Mumford [37] for surfaces, had shown that the map α_X has a "huge" kernel, assuming that X admits a global algebraic p -form with p at least 2 (and that $k = \mathbb{C}$). In contrast with this, Roitman shows in [42] that α_X induces an isomorphism on the torsion subgroups (prime to the characteristic of k).

The main point in his argument is the rigidity result: Suppose we have a family of zero-cycles on X , parametrized by an algebraic curve C , which are n -torsion mod rational equivalence, with n prime to the characteristic of k . Then the family is *constant* mod rational equivalence. The argument is quite simple: Let $C(k)$ be the set of k -points of C and let $\text{CH}_0(X)_n$ be the n -torsion subgroup of $\text{CH}_0(X)$. Sending $x \in C(k)$ to the corresponding 0-cycle gives the map

$$\rho: C(k) \rightarrow \text{CH}_0(X)_n;$$

one easily shows that ρ extends to a group homomorphism from the k -points of the Jacobian variety

$$J(\rho): J(C)(k) \rightarrow \mathrm{CH}_0(X)_n.$$

Since k is algebraically closed, the group $J(C)(k)$ is n -divisible, hence $J(\rho)$ is the zero map. Since $J(C)(k)$ is generated by the differences $x - y$, where x and y are k -points of C , this shows that $\rho(x) = \rho(y)$ for all $x, y \in C(k)$. The fundamental rigidity result, theorem 8.2 below, is essentially a formal version of this result; various other extensions, with application to K -theory, had been given by Suslin [46], [47], Gillet-Thomason [27] and Gabber [22].

DEFINITION 8.1. A presheaf \mathcal{F} on \mathbf{Sch}/k is called *homotopy invariant* if the map

$$p_1^*: \mathcal{F}(X) \rightarrow \mathcal{F}(X \times \mathbb{A}^1)$$

is an isomorphism for all X .

Theorem 8.2. *Let \mathcal{F} be presheaf on \mathbf{Sch}/k which*

- (1) *is homotopy invariant*
- (2) *has transfers*
- (3) *is n -torsion: $n\mathcal{F}(T) = 0$ for all k -schemes T , where n is prime to the exponential characteristic of k .*

Let x be a smooth point on a k -variety X , X_x^h the henselization of X at x (see remark 5.2) and let

$$i_x: \mathrm{Spec} k \rightarrow X_x^h$$

be the inclusion. Then the map

$$i_0^*: \mathcal{F}(X_x^h) \rightarrow \mathcal{F}(\mathrm{Spec} k).$$

is an isomorphism.

It follows from theorem 8.2 and remark 6.3 that the h-sheaf associated to a homotopy invariant presheaf with transfers \mathcal{F} and the the constant h-sheaf with value $\mathcal{F}(\mathrm{Spec} k)$ have the same n -torsion and n -cotorsion, assuming that k is algebraically closed. This implies the fundamental cohomological rigidity theorem

Theorem 8.3. *Let k be an algebraically closed field, and let \mathcal{F} be a homotopy invariant presheaf on \mathbf{Sch}/k which admits transfers. Denote by $\tilde{\mathcal{F}}_h$ the sheafification of \mathcal{F} for the h-topology. Then for all n prime to $\mathrm{char}(k)$, there is a canonical isomorphism*

$$\mathrm{Ext}_h^*(\tilde{\mathcal{F}}_h, \mathbb{Z}/n) \rightarrow \mathrm{Ext}_{\mathrm{Ab}}^*(\mathcal{F}(\mathrm{Spec} k), \mathbb{Z}/n).$$

REMARK 8.4. The proof in [49] assumes characteristic zero to allow the use of resolution of singularities, which enables one to show that each k -scheme of finite type admits an h-cover which is smooth over k ; the result of de Jong noted in remark 6.3 allows the proof to go through in arbitrary characteristic.

9. CHANGE OF TOPOLOGY

Suppose we have two Grothendieck topologies on \mathbf{Sch}/k , \mathfrak{T} and \mathfrak{T}' , such that \mathfrak{T} is finer than \mathfrak{T}' , i.e., each cover in \mathfrak{T}' is a cover in \mathfrak{T} .

We may take a sheaf for the topology \mathfrak{T}' and sheafify it for the topology \mathfrak{T} , defining the functor

$$i^* : \mathrm{Sh}_{\mathfrak{T}'} \rightarrow \mathrm{Sh}_{\mathfrak{T}}$$

For example, we may compare the h-, qfh- and étale topologies,

$$\mathbf{Sch}/k_{\mathrm{h}} \xrightarrow{\alpha} \mathbf{Sch}/k_{\mathrm{qfh}} \xrightarrow{\beta} \mathbf{Sch}/k_{\mathrm{ét}}.$$

The main comparison result is

Theorem 9.1. *Let \mathcal{F} be an étale sheaf and let \mathcal{G} be a qfh-sheaf on \mathbf{Sch}/k . Then*

$$\begin{aligned} \mathrm{Ext}_{\mathrm{ét}}^*(\mathcal{F}, \mathbb{Z}/n) &= \mathrm{Ext}_{\mathrm{qfh}}^*(\beta^* \mathcal{F}, \mathbb{Z}/n) \\ \mathrm{Ext}_{\mathrm{qfh}}^*(\mathcal{G}, \mathbb{Z}/n) &= \mathrm{Ext}_{\mathrm{h}}^*(\alpha^* \mathcal{G}, \mathbb{Z}/n) \end{aligned}$$

The proof is fairly straightforward: the comparison of the étale and qfh cohomology relies on the structure of qfh-covers (theorem 6.2(ii)) and some elementary facts on finite covers of strictly hensel schemes. One then compares the h-cohomology with étale cohomology, using the structure of h-covers (theorem 6.2(i)) and the Künneth formula for étale cohomology.

10. SUSLIN COHOMOLOGY OF qfh-SHEAVES

We now have all the main ingredients needed to relate Suslin homology and étale cohomology: the representability theorem 7.1 and the rigidity theorem 8.3. Helped along by the comparison theorem 9.1, a straightforward spectral sequence argument completes the proof. It is technically useful to work in a somewhat more general setting, working with an arbitrary presheaf rather than the constant presheaf \mathbb{Z} .

Let \mathcal{F} be a presheaf on \mathbf{Sch}/k , and let X be in \mathbf{Sch}/k . Applying \mathcal{F} to the cosimplicial scheme $X \times \Delta^*$ (as in §2) gives the simplicial abelian group $\mathcal{F}(X \times \Delta^*)$, and the associated (homological) complex $\mathcal{F}_*(X)$:

$$\mathcal{F}_n(X) = \mathcal{F}(X \times \Delta^n).$$

This forms the presheaves \mathcal{F}_n on \mathbf{Sch}/k , and the complex of presheaves \mathcal{F}_* . For an abelian group A , set

$$\begin{aligned} C_*(\mathcal{F}) &:= \mathcal{F}_*(\mathrm{Spec} k) = \mathcal{F}(\Delta^*) \\ H_*^{\mathrm{sing}}(\mathcal{F}, A) &:= H_*(C_*(\mathcal{F}) \otimes^L A) \\ H_{\mathrm{sing}}^*(\mathcal{F}, A) &:= H^*(\mathrm{RHom}(C_*(\mathcal{F}), A)). \end{aligned}$$

Let $\tilde{\mathcal{F}}_n$ qfh denote the qfh-sheaf associated to \mathcal{F}_n and $\tilde{\mathcal{F}}_{\mathrm{qfh}}$ the qfh-sheaf associated to \mathcal{F}_* . We also write $C_*(\mathcal{F})$ for the complex of constant sheaves.

Theorem 10.1. *Let k be an algebraically closed field, and let $n > 0$ be prime to $\mathrm{char}(k)$. Let \mathcal{F} be a presheaf on \mathbf{Sch}/k which admits transfers. Then there is a canonical isomorphism*

$$H_{\mathrm{sing}}^*(\mathcal{F}, \mathbb{Z}/n) \cong \mathrm{Ext}_{\mathrm{qfh}}^*(\tilde{\mathcal{F}}_{\mathrm{qfh}}, \mathbb{Z}/n).$$

Using theorem 9.1, and the fact that qfh-sheaves admit transfers (§7), theorem 10.1 implies

Corollary 10.2. *Let \mathcal{F} be a qfh-sheaf on \mathbf{Sch}/k , with k algebraically closed. Then there is a canonical isomorphism*

$$H_{sing}^*(\mathcal{F}, \mathbb{Z}/n) \cong Ext_{\acute{e}t}^*(\mathcal{F}, \mathbb{Z}/n)$$

for all n prime to $\text{char}(k)$.

Taking $\mathcal{F} = \mathbb{Z}_{\text{qfh}}(X)$ and using theorem 7.1 and formula (5.2) gives the main result:

Corollary 10.3. *Let X be a scheme of finite type over an algebraically closed field k , and let n be prime to $\text{char}(k)$. Then there is a natural isomorphism*

$$H_{sing}^*(X, \mathbb{Z}/n) \cong H_{\acute{e}t}^*(X, \mathbb{Z}/n).$$

The proof of theorem 10.1 starts by considering the two spectral sequences

$$I_1^{p,q} = \text{Ext}_{\text{qfh}}^p((\tilde{\mathcal{F}}_q)_{\text{qfh}}, \mathbb{Z}/n) \implies \text{Ext}^{p-q}((\tilde{\mathcal{F}}_*)_{\text{qfh}}, \mathbb{Z}/n),$$

$$II_2^{p,q} = \text{Ext}_{\text{qfh}}^p(H_q((\tilde{\mathcal{F}}_*)_{\text{qfh}}), \mathbb{Z}/n) \implies \text{Ext}^{p-q}((\tilde{\mathcal{F}}_*)_{\text{qfh}}, \mathbb{Z}/n).$$

The comparison of qfh-cohomology and étale cohomology (theorem 9.1), and the homotopy invariance of étale cohomology

$$H_{\acute{e}t}^*(X, \mathbb{Z}/n) \cong H_{\acute{e}t}^*(X \times \mathbb{A}^1, \mathbb{Z}/n)$$

lead to a proof that the projections $X \times \Delta^p \rightarrow X$ induces isomorphisms

$$\text{Ext}_{\text{qfh}}^p(\tilde{\mathcal{F}}_{\text{qfh}}, \mathbb{Z}/n) \cong \text{Ext}_{\text{qfh}}^p((\tilde{\mathcal{F}}_q)_{\text{qfh}}, \mathbb{Z}/n).$$

This implies the degeneration of the spectral sequence I at E_1 , giving the isomorphism

$$\text{Ext}_{\text{qfh}}^*(\tilde{\mathcal{F}}_{\text{qfh}}, \mathbb{Z}/n) \cong \text{Ext}_{\text{qfh}}^*((\tilde{\mathcal{F}}_*)_{\text{qfh}}, \mathbb{Z}/n).$$

By the homotopy invariance of the functors (2.3), the homology presheaf

$$H_q((\tilde{\mathcal{F}}_*)_{\text{qfh}})$$

forms a homotopy invariant presheaf on Sch/k ; the transfers for the qfh-sheaves $(\tilde{\mathcal{F}}_q)_{\text{qfh}}$ give transfers for $H_q((\tilde{\mathcal{F}}_*)_{\text{qfh}})$. This allows one to use the comparison with h-cohomology (theorem 9.1) and the rigidity theorem 8.3 to compare the spectral sequence II with the spectral sequence

$$III_2^{p,q} = \text{Ext}_{Ab}^p(H_q(\mathcal{F}_*(\text{Spec } k), \mathbb{Z}/n) \implies \text{Ext}_{Ab}^{p-q}(\mathcal{F}_*(\text{Spec } k), \mathbb{Z}/n),$$

giving the isomorphism

$$\text{Ext}_{Ab}^*(\mathcal{F}_*(\text{Spec } k), \mathbb{Z}/n) \cong \text{Ext}_{\text{qfh}}^*((\tilde{\mathcal{F}}_*)_{\text{qfh}}, \mathbb{Z}/n)$$

and completing the proof.

11. SUSLIN HOMOLOGY AND BLOCH'S HIGHER CHOW GROUPS

To complete the discussion, it is necessary to relate Suslin homology and Bloch's higher Chow groups.

For X in \mathbf{Sch}/k , and Y normal, let $Z_0(X)(Y)$ denote the free abelian group on the subvarieties W of $X \times Y$ which are *quasi-finite* over Y . As in §4, sending a smooth Y to $Z_0(X)(Y)$ defines a contravariant functor on \mathbf{Sm}/k . Taking Y to be the cosimplicial scheme Δ^* , and taking the associated homological complex defines the complex $Z_*(X)$, with

$$Z_n(X) = Z_0(X)(\Delta^n).$$

Suppose X has pure dimension d over k . As a subvariety W of $X \times \Delta^p$ which is quasi-finite over Δ^p obviously has the proper intersection with all faces, there is the inclusion of complexes

$$(11.1) \quad Z_*(X) \rightarrow \mathcal{Z}^d(X, *).$$

Suslin [48] has shown

Theorem 11.1. *Suppose that X is affine. Then the inclusion (11.1) is a quasi-isomorphism.*

Let $\mathrm{CH}^q(X, p; \mathbb{Z}/n)$ denote the homology

$$\mathrm{CH}^q(X, p; \mathbb{Z}/n) = H_p(\mathcal{Z}^q(X, *) \otimes \mathbb{Z}/n) = H_p((\mathcal{Z}^q(X, *) \otimes^L \mathbb{Z}/n)).$$

There is an analog of theorem 7.1:

Theorem 11.2. *There is a unique extension of the functor $Z_0(X)[1/p]$ on \mathbf{Sm}/k to a qfh-sheaf $z_0(X)$ on \mathbf{Sch}/k*

Applying theorem 10.1 gives

Proposition 11.3. *Let n be prime to $\mathrm{char}(k)$ and suppose X is affine of dimension d over k . There is a natural isomorphism*

$$\mathrm{CH}^d(X, *; \mathbb{Z}/n)^\vee = H_*^{\mathrm{sing}}(z_0(X), \mathbb{Z}/n)^\vee \cong \mathrm{Ext}_{\mathrm{qfh}}^*(z_0(X), \mathbb{Z}/n).$$

Here M^\vee is the dual

$$M^\vee := \mathrm{Hom}_{\mathbb{Z}/n}(M, \mathbb{Z}/n)$$

of a \mathbb{Z}/n -module M .

The qfh-sheaves $z_0(X)$ are contravariantly functorial in X for open immersions, and covariantly functorial for proper maps. If Y is a closed subscheme of X with complement U , the following sequence

$$(11.2) \quad 0 \rightarrow z_0(Y) \rightarrow z_0(X) \rightarrow z_0(U)$$

is easily seen to be exact. Letting $\tilde{z}_0(X)_h$ denote the h-sheaf associated to $z_0(X)$, there is the

Lemma 11.4. *The sequence*

$$(11.3) \quad 0 \rightarrow \tilde{z}_0(Y)_h \rightarrow \tilde{z}_0(X)_h \rightarrow \tilde{z}_0(U)_h \rightarrow 0$$

induced from the sequence (11.2) is an exact sequence of h-sheaves on \mathbf{Sch}/k .

REMARK 11.5. As mentioned in §4, the Suslin homology of the functor $C_0(X)$ is an algebraic version of homology; the Suslin homology of the functor $Z_0(X)$ can similarly be viewed as an algebraic version of *Borel-Moore homology*. In fact, recall from theorem 7.1 that the functor $C_0(X)[1/p]$ extends to the qfh-sheaf $c_0(X)$ on \mathbf{Sch}/k . The h-sheaf $\tilde{c}_0(-)_h$ associated to the qfh-sheaf $c_0(-)$ satisfies a Mayer-Vietoris property, giving the exact sequence

$$(11.4) \quad 0 \rightarrow \tilde{c}_0(U \cap V)_h \rightarrow \tilde{c}_0(U)_h \oplus \tilde{c}_0(V)_h \rightarrow \tilde{c}_0(U \cup V)_h \rightarrow 0$$

By theorem 10.1, the sequences (11.3) and (11.4) give rise to a localization sequence for the mod n Suslin homology $H_*^{\text{sing}}(Z_0(-), \mathbb{Z}/n)$ and a Mayer-Vietoris sequence for the mod n Suslin homology $H_*^{\text{sing}}(-, \mathbb{Z}/n)$ (assuming n prime to the characteristic). In [50], modifications of the sequences (11.3) and (11.4) give rise to a localization sequence for $H_*^{\text{sing}}(Z_0(-), \mathbb{Z})$ of $Z_0(-)$ and a Mayer-Vietoris sequence for $H_*^{\text{sing}}(-, \mathbb{Z})$ (assuming characteristic zero).

If X is proper over k we have

$$z_0(X) = c_0(X).$$

By theorem 9.1, formula (5.2) and corollary 10.2, we have the isomorphisms

$$(11.5) \quad \text{Ext}_h^*(\tilde{z}_0(X)_h, \mathbb{Z}/n) \cong H_{\text{ét}}^*(X, \mathbb{Z}/n)$$

for X proper. Using the long exact Ext-sequence arising from the exact sequence of lemma 11.4, and the corresponding long exact Gysin sequence for étale cohomology with compact supports, one extends the isomorphism (11.6) to the isomorphism

$$(11.6) \quad \text{Ext}_h^*(\tilde{z}_0(X)_h, \mathbb{Z}/n) \cong H_c^*(X, \mathbb{Z}/n)$$

to arbitrary X ; here H_c^* is the étale cohomology with compact supports.

With the help of (11.6), one arrives at the following comparison of the mod- n higher Chow groups, and étale cohomology for affine X :

Theorem 11.6. *Let X be an affine variety over an algebraically closed field k , and let $n > 0$ be an integer prime to $\text{char}(k)$. Assume that $q > d := \dim(X)$. Then there is a natural isomorphism*

$$CH^q(X, p; \mathbb{Z}/n) \cong H_c^{2(d-q)+p}(X, \mathbb{Z}/n(d-q))^\vee.$$

The proof uses the homotopy property to replace X with $X \times \mathbb{A}^{q-d}$, which reduces to the case $q = d$; one then applies proposition 11.3 and the isomorphism (11.6). Using Poincaré duality, theorem 8.3 implies

Corollary 11.7. *Let X be a smooth affine variety over an algebraically closed field k , and let $n > 0$ be an integer prime to $\text{char}(k)$. Assume that $q \geq d := \dim(X)$. Then there is a natural isomorphism*

$$CH^q(X, p; \mathbb{Z}/n) \cong H_{\text{ét}}^{2d-p}(X, \mathbb{Z}/n(q)).$$

The results 11.2 and 11.2 extend to quasi-projective X (resp. smooth quasi-projective X) if $\text{char}(k) = 0$, using the localization property for the higher Chow groups [5] and the analogous Gysin sequence for étale cohomology with compact supports.

12. EPILOGUE

We have not described the beautiful constructions and results in the fundamental papers [50], [52] and [20], which form the foundations for many of the constructions we have described. We omitted as well mention of the works on Lawson homology and related topics [17], [18], and [16], which formed a large part of the motivation for many of the constructions of [50] and [20]. We have also not described the various constructions of triangulated motivic categories and motivic complexes, in [23],[28], [34], [36], [53] and [33]. Presumably, the categorical constructions all lead to equivalent categories and the complexes all yield equivalent cohomologies, but this is at present not known.

More recently, Suslin and Voevodsky [51] have reduced the Quillen-Lichtenbaum conjectures for motivic cohomology to the *Bloch-Kato conjecture* which asserts that the *Galois symbol* on Milnor K -theory of a field F defines an isomorphism

$$K_q^M(F)/n \rightarrow H_{\text{ét}}^q(F, \mu_n^{\otimes q})$$

for all n prime to the characteristic of F . Relying on results of Rost [43], [44], Voevodsky has given a proof of the mod 2 Bloch-Kato conjecture (see [54]), which thus completely solves the mod 2 Quillen-Lichtenbaum conjecture for motivic cohomology. Using the Bloch-Lichtenbaum spectral sequence [6] relating K -theory and motivic cohomology, Weibel [55] has shown how to compute the mod 2 K -theory of \mathbb{Z} ; this has recently been extended by Kahn [30] to a computation of the mod 2 K -theory of all number rings, verifying that mod 2 algebraic K -theory agrees with mod 2 étale K -theory for all number rings. There is a whole host of unanswered questions in the area of motivic cohomology and algebraic K -theory; the new viewpoint offered by Voevodsky, Suslin and others will surely lead to further breakthroughs.
