Abstract

Logarithmic signatures for finite groups are the essential constituent of public key cryptosystems MST$_1$ and MST$_3$. Especially they form the main component of the private key of MST$_3$. Constructing new classes of logarithmic signatures having features that do not share with the well-known class of transversal or fused transversal logarithmic signatures, has become a vital issue regarding the use of MST$_3$. For this purpose Baumeister and de Wiljes recently present an interesting method of constructing aperiodic logarithmic signatures for abelian groups. In this paper we introduce the concept of strongly aperiodic logarithmic signatures and show their constructions for abelian p-groups on the basis of the Baumeister-de Wiljes method.

Keywords. Public-key cryptosystem MST$_3$, aperiodic logarithmic signature, strongly aperiodic logarithmic signature, Baumeister-de Wiljes method.

1 Introduction

The public key cryptosystems MST$_1$ [8] and MST$_3$ [5], [12] are developed on the basis of logarithmic signatures, a kind of factorization of finite groups. The basic idea for building MST$_3$ is to construct trapdoor one-way functions using random covers for finite non-abelian groups having a large center. An integrated trapdoor information, which forms the main part of the private key of the scheme, employs logarithmic signatures of the center. The Suzuki 2-groups have been proposed as the underlying groups for an instantiation of MST$_3$. The first analysis of the simple version of MST$_3$ [5] due to Magliveras, Svaba, Tran van Trung and Zajac [9] shows that transversal logarithmic signatures are unfit for use in the scheme. A further investigation of Blackburn, Cid and Mullan [2] proves that the use of fused transversal logarithmic signatures also makes the simple version of MST$_3$ insecure. However, for the strengthened version of MST$_3$ [12], it is shown that fused transversal logarithmic signatures still withstand the powerful Matrix-Permutation attack, see [12]. It is therefore essential to study further classes of logarithmic signatures having features that would be more suitable for use in public key cryptosystems like MST$_3$.

In a recent paper [1] Baumeister and de Wiljes propose an interesting method for contracting aperiodic logarithmic signatures for abelian groups, in particular, for abelian 2-groups, that thwart
the Blackburn-Cid-Mullan attack. It is worthy to mention that transversal or fused transversal logarithmic signatures have the property of being periodic. In this paper we introduce the concept of strongly aperiodic logarithmic signatures and present their constructions for abelian p-groups based on Baumeister-de Wiljes method. Aperiodic and strongly aperiodic logarithmic signatures provide classes of logarithmic signatures having features befitting the use of MST$_3$. Moreover, we are convinced that strongly aperiodic logarithmic signatures for abelian groups are also of theoretical interest in their own right.

2 Preliminaries

In this section we briefly present notation, definitions and some basic facts about logarithmic signatures, covers for finite groups and their induced mappings. For more details the reader is referred to [7], [8]. The group theoretic notation used is standard and may be found in any textbook.

Let $G$ be a finite abstract group, we define the width of $G$ to be the positive integer $w = \lceil\log|G|\rceil$. Let $\mathcal{S}$ be a subset of $G$ and let $\alpha = [A_1, A_2, \ldots, A_s]$ be an ordered collection of ordered subsets $A_i = \{a_{i1}, \ldots, a_{ir_i}\}$ of $G$, such that $\sum_{i=1}^{s} |A_i|$ is bounded by a polynomial in $\log |\mathcal{S}|$. Then we say that $\alpha$ is a cover for $\mathcal{S}$, if every product $a_{i1,j_1} \cdots a_{is,js}$ lies in $\mathcal{S}$ and if every $g \in \mathcal{S}$ can be written as

$$g = a_{i1,j_1} \cdots a_{is,js}$$

(2.1)

with $a_{i,j} \in A_i$. If, moreover, the expression in (2.1) is unique for every $g \in \mathcal{S}$, then $\alpha$ is called a logarithmic signature for $\mathcal{S}$. We denote by $\mathcal{C}(\mathcal{S} \subseteq G)$ and $\Lambda(\mathcal{S} \subseteq G)$ the respective collections of covers and logarithmic signatures for $\mathcal{S} \subseteq G$. When $\mathcal{S} = G$, we simply write $\mathcal{C}(G)$ and $\Lambda(G)$ instead of $\mathcal{C}(\mathcal{S} \subseteq G)$ and $\Lambda(\mathcal{S} \subseteq G)$. A cover or a logarithmic signature $\alpha = [A_1, A_2, \ldots, A_s]$ for a group $G$ is said to be proper if $|A_i| \neq 1$ and $A_i \neq G$, for every $i$, $1 \leq i \leq s$. We assume that all covers and logarithmic signatures are proper. The product $a_{i1,j_1} \cdots a_{is,js}$ in (2.1) is called a factorization of $g$ with respect to $\alpha$.

Let $\alpha = [A_1, \ldots, A_s]$ be a cover for $G$ with $r_i = |A_i|$, then the $A_i$ are called the blocks of $\alpha$ and the vector $(r_1, \ldots, r_s)$ of block lengths $r_i$ the type of $\alpha$. We define the length of $\alpha$ to be the integer $\ell(\alpha) = \sum_{i=1}^{s} r_i$.

Let $\Gamma = \{(G_\ell, \alpha_\ell)\}_{\ell \in \mathbb{N}}$ be a family of pairs, indexed by the security parameter $\ell$, where the $G_\ell$ are groups in a common representation, and where $\alpha_\ell$ is a specific cover for $G_\ell$ of length polynomial in $\ell$. We say that $\Gamma$ is tame if there exists a probabilistic polynomial time algorithm $A$ such that for each $g \in G_\ell$, $A$ accepts $(\alpha_\ell, g)$ as input, and outputs a factorization of $g$ with respect to $\alpha_\ell$ (as in equation (2.1)) with overwhelming probability of success. We say that $\Gamma$ is wild if for any probabilistic polynomial time algorithm $A$, the probability that $A$ succeeds in factorizing a random element $g$ of $G$ is negligible. In other words $\Gamma$ is tame if there exists an algorithm by means of which the factorization in (2.1) for each instance $\{(G, \alpha_\ell)\}$ can be achieved in time polynomial in $\lceil\log |G_\ell|\rceil$; and $\Gamma$ is wild if it is not tame. Often we simply say $\alpha_\ell$ is tame or wild.

For finite groups there are instances $\{(G, \alpha_\ell)\}$ where the factorization in (2.1) is believed to be hard: For example, let $q$ be a prime power for which the discrete logarithm problem in the multiplicative group of a finite field $\mathbb{F}_q$ is believed to be hard. Suppose that $2^{\ell - 1} \leq q - 1 < 2^{\ell}$, and let $G_\ell$ be the multiplicative group $\mathbb{F}_q^*$ just mentioned. Let $f$ be a generator of $G_\ell$. If $\alpha_\ell =$
[A_1, A_2, \ldots, A_\ell], where A_i = [1, f^{2^i-1}], then \alpha_\ell is a cover of G_\ell, and factorization with respect to \alpha_\ell amounts to solving the discrete logarithm problem (DLP) in G_\ell.

Let \alpha = [A_1, A_2, \ldots, A_s] be a cover of type (r_1, r_2, \ldots, r_s) for S \subseteq \mathcal{G} with A_i = [a_{i,1}, a_{i,2}, \ldots, a_{i,r_i}] and let m = \prod_{i=1}^{s} r_i. Let m_1 = 1 and m_i = \prod_{j=1}^{i-1} r_j for i = 2, \ldots, s. Let \tau denote the canonical bijection from \mathbb{Z}_{r_1} \oplus \mathbb{Z}_{r_2} \oplus \cdots \oplus \mathbb{Z}_{r_s} on \mathbb{Z}_m; i.e.

\tau : \mathbb{Z}_{r_1} \oplus \mathbb{Z}_{r_2} \oplus \cdots \oplus \mathbb{Z}_{r_s} \rightarrow \mathbb{Z}_m

\tau(j_1, j_2, \ldots, j_s) := \sum_{i=1}^{s} j_im_i.

Using \tau we now define the surjective mapping \check{\alpha} induced by \alpha.

\check{\alpha} : \mathbb{Z}_m \rightarrow S

\check{\alpha}(x) := a_{1,j_1} \cdot a_{2,j_2} \cdots a_{s,j_s},

where (j_1, j_2, \ldots, j_s) = \tau^{-1}(x). Since \tau and \tau^{-1} are efficiently computable, the mapping \check{\alpha}(x) is efficiently computable.

Conversely, given a cover \alpha and an element y ∈ S, to determine any element x ∈ \check{\alpha}^{-1}(y) it is necessary to obtain any one of the possible factorizations of type (2.1) for y and determine indices j_1, j_2, \ldots, j_s such that y = a_{1,j_1} \cdot a_{2,j_2} \cdots a_{s,j_s}. This is possible if and only if \alpha is tame. Once a vector (j_1, j_2, \ldots, j_s) has been determined, \check{\alpha}^{-1}(y) = \tau(j_1, j_2, \ldots, j_s) can be computed efficiently.

Two covers (logarithmic signatures) \alpha, \beta are said to be equivalent if \check{\alpha} = \check{\beta}.

It is worth noting that random covers and logarithmic signatures have been used to construct pseudorandom number generators which are suitable for cryptographic applications [10], [6].

3 The cryptosystem MST₃

Let \mathcal{G} be a finite non-abelian group with nontrivial center \mathcal{Z} such that \mathcal{G} does not split over \mathcal{Z}. Assume further that \mathcal{Z} is sufficiently large so that exhaustive search problems are computationally not feasible in \mathcal{Z}. We describe the strengthened version of MST₃, see [12].

Alice chooses a large group \mathcal{G} as described above and generates

1. a tame logarithmic signature \beta = [B_1, B_2, \ldots, B_s] := (b_{ij}) of type (r_1, r_2, \ldots, r_s) for \mathcal{Z}.
2. a random cover \alpha = [A_1, A_2, \ldots, A_s] := (a_{ij}) of the same type as \beta for a certain subset \mathcal{J} of \mathcal{G} such that A_1, \ldots, A_s \subseteq \mathcal{G} \setminus \mathcal{Z}.

She further selects t_0, t_1, \ldots, t_s ∈ \mathcal{G} \setminus \mathcal{Z}, a homomorphism f : \mathcal{G} \rightarrow \mathcal{Z} and computes:

3. \gamma = (h_{ij}), \quad h_{ij} = t_i^{-1} \cdot a_{ij} \cdot f(a_{ij}) \cdot b_{ij} \cdot t_i

Alice publishes her public key \((\alpha, \gamma)\), keeping \((\beta, t_0, t_1 \ldots, t_s, f)\) as her private key.

To encrypt a message \(x \in \mathbb{Z}\) Bob chooses a random number \(R \in \mathbb{Z}/|\mathbb{Z}|\), \(R \neq 0\), and computes 
\[y_1 = \alpha(R) \cdot x, \quad y_2 = \gamma(R) \cdot x = t_0^{-1} \cdot \alpha(R) \cdot f(\alpha(R)) \cdot \beta(R) \cdot t_s \cdot x,\]
and sends \(y = (y_1, y_2)\) to Alice.

To decrypt \(y = (y_1, y_2)\) Alice computes \(\tilde{\beta}(R) = f(\tilde{\alpha}(R))^{-1} \cdot y_1^{-1} \cdot t_0 \cdot y_2 \cdot t_s^{-1} = f(y_1)^{-1} \cdot y_1^{-1} \cdot t_0 \cdot y_2 \cdot t_s^{-1}\) by using the fact that \(f(y_1) = f(\tilde{\alpha}(R))\), she then computes \(R\) from \(\tilde{\beta}(R)\) which is efficiently computable as \(\beta\) is tame. She computes \(\tilde{\alpha}(R)\) and recovers \(x\) from \(y_1\).

In the description above if we choose \(f\) as the trivial homomorphism i.e. \(f(g) = 1_G\) for all \(g \in G\), we obtain the simple version of the cryptosystem \(MST_3\) [5]. The use of nontrivial homomorphism \(f\) considerably strengthens the scheme as shown in [12]. The homomorphism \(f\) is used to mask the secret logarithmic signature \(\alpha\) with information computed from cover \(\alpha\). We refer the reader to [12] and [5] for more detailed information about \(MST_3\).

As an instantiation of \(MST_3\) it has been suggested that the Suzuki 2-groups [3] might be used for the underlying groups [5] and [12]. Let \(q = 2^m\) with \(3 \leq m \in \mathbb{N}\) such that the field \(\mathbb{F}_q\) has a nontrivial automorphism \(\theta\) of odd order, i.e. \(m\) is not a power of 2. Then a Suzuki 2-group \(G\) can be briefly described as follows.

\[G := \{(a, b) \in \mathbb{F}_q \times \mathbb{F}_q \mid (a_1, b_1) \times (a_2, b_2) = (a_1 + a_2, b_1 + b_2 + a_0^2 a_2)\}\]

Thus \(G\) has order \(q^2\) and \(\mathbb{Z}(G) = \Phi(G) = G' = \Omega_1(G) = \{(0, b) \mid b \in \mathbb{F}_q\}\). In particular the center \(\mathbb{Z}(G)\) is elementary abelian of order \(q\).

### 4 Classes and transformations of logarithmic signatures

In this section we briefly discuss classes of logarithmic signatures and basic transformations on logarithmic signatures for a group \(G\).

Let \(\gamma : 1_G = G_0 < G_1 < \cdots < G_s = G\) be a chain of subgroups of \(G\), and let \(A_i\) be an ordered, complete set of right (or left) coset representatives of \(G_{i-1}\) in \(G_i\). Then \([A_1, \ldots, A_s]\) forms a logarithmic signature for \(G\), called exact transversal logarithmic signature. We denote the collection of all exact transversal logarithmic signatures for a group \(G\) by \(ET(G)\). A logarithmic signature \(\alpha\) for a group \(G\) is called transversal if \(\alpha\) is equivalent to a \(\beta \in ET(G)\), otherwise \(\alpha\) is called non-transversal. Further, if none of the blocks of \(\alpha\) is a coset of a non-trivial subgroup of \(G\), then \(\alpha\) is called totally non-transversal. We will denote the class of transversal, non-transversal, and totally non-transversal logarithmic signatures for \(G\) by \(T(G), NT(G),\) and \(TNT(G)\) respectively.

We list some basic transformations on logarithmic signatures. By applying certain transformations on a logarithmic signature, new logarithmic signatures will be derived. Let \(\alpha = [A_1, \ldots, A_s] \in \Lambda(G)\).

- **Element shuffle**: Permute the elements within each block of \(\alpha\).
- **Block shuffle**: If \(G\) is non-abelian, permuting two blocks of \(\alpha\) may result in a cover for a certain subset of \(G\). If \(G\) is abelian, then the result of a block shuffle is indeed a logarithmic signature.
• **Two sided transformation:** Let $g_0, g_1, \ldots, g_s \in G$. Define a new logarithmic signature $\beta = [B_1, \ldots, B_s]$ by $B_i = g_i^{-1} A_i g_i$. Then $\beta$ is called a two sided transform of $\alpha$. When $g_0 = g_s = 1$, we say that $\beta$ is a sandwich of $\alpha$. When $g_0 = 1$, $\beta$ is said to be a right translation of $\alpha$ by $g_s$. If $g_s = 1$, then $\beta$ is called a left translation of $\alpha$ by $g_0$.

• **Fusion:** If $G$ is non-abelian, then replacing two consecutive blocks $A_i$ and $A_{i+1}$, $1 \leq i \leq s-1$ by a single block $B = A_i A_{i+1} := \{ xy \mid x \in A_i, y \in A_{i+1} \}$ will result in a logarithmic signature. $B$ is called a fused block. If $G$ is abelian, the fusion transformation can be done on any two blocks of $\alpha$.

• **Automorphism action:** If $\varphi$ is an automorphism of $G$, then $\beta = [B_1, \ldots, B_s]$ with $B_i = \varphi(A_i)$, $1 \leq i \leq s$, is a logarithmic signature for $G$.

## 5 Aperiodic logarithmic signatures and Baumeister-de Wiljes construction

Investigating tame aperiodic logarithmic signatures for abelian groups is a problem of theoretical interest and of practical importance. They present a new class of logarithmic signatures beyond the well-known classes of transversal and their fused logarithmic signatures which are all periodic. Regarding cryptosystem MST$_3$ aperiodic logarithmic signatures appear to be especially significant.

**Definition 5.1** A non-empty subset $X$ of a group $G$ is called periodic if there exists an element $g \in G \setminus \{1_G\}$ such that $g X = X$. Such an element $g$ is called a period of $X$.

The set of all periods of $X$ will be denoted by $P(X)$, i.e. $P(X) = \{ g \in G \setminus \{1_G\} : g X = X \}$.

**Definition 5.2** A logarithmic signature $\alpha = [A_1, \ldots, A_s] \in \Lambda(G)$ is called aperiodic if none of the blocks $A_i$ is periodic.

We denote the set of all aperiodic logarithmic signatures for $G$ by $A(G)$.

In a recent paper of Baumeister and de Wiljes [1], the authors present an interesting method for constructing aperiodic signatures for abelian groups. The method is based on the theory in the book of Szabó [13], and it describes an approach to constructing aperiodic logarithmic signatures for abelian groups. The method is not an algorithm in the strict sense, since the requirement posed by the method prohibits quickly its computational feasibility even for groups of moderate order. However, the basic idea of the method has proved to be useful, since it provides a technique for searching aperiodic logarithmic signatures for abelian groups. We now describe the Baumeister-de Wiljes construction.

**Baumeister-de Wiljes construction**

Let $G$ be a finite abelian group. Let $H$ be a subgroup of $G$ and let $T$ be a transversal of $H$ in $G$ (i.e. $T$ is a complete set of coset representatives of $H$ in $G$).
(i) Let $\theta = [T_1, \ldots, T_s]$ be a logarithmic signature of type $(r_1, \ldots, r_s)$ for $T$, where $T_i = \{t_{i,1}, \ldots, t_{i,r_i}\}$.

(ii) Suppose that for each $i$ with $1 \leq i \leq s$ there exists a collection
\[ L_i = \{A_{i,1}, \ldots, A_{i,r_i}\} \]
of subsets $A_{i,j}$ of $H$ such that any choice $[A_{1,j_1}, \ldots, A_{s,j_s}]$ with $A_{i,j_i} \in L_i$ forms a logarithmic signature for $H$.

(iii) Then $\beta = [B_1, \ldots, B_s]$ defined by $B_i = t_{i,1}A_{i,1} \cup \ldots \cup t_{i,r_i}A_{i,r_i}$, for $1 \leq i \leq s$ forms a logarithmic signature of type $(\ell_1, \ldots, \ell_s)$ for $G$, where $\ell_i = \sum_{j=1}^{r_i} |A_{i,j}|$.

For any subsets $A, B$ of a group $G$ we say that $B$ is a translate of $A$ if there is an element $g \in G$ such that $gA = B$. The translate $B$ is called proper if $A \neq B$.

Baumeister and de Wiljes give the following characterization of aperiodicity for the constructed logarithmic signature $\beta$.

**Proposition 1** Suppose that $A_{i,j}$ is not a translate of $A_{i,k}$ for any $j, k \in \{1, \ldots, r_i\}$. Then $B_i$ is periodic if and only if
\[ \bigcap_{j=1}^{r_i} P(A_{i,j}) \neq \emptyset. \]

The main idea of Baumeister-de Wiljes construction of aperiodic logarithmic signatures is to find sets $L_i$ satisfying condition (ii).

**Example 1** Let $G$ be an elementary abelian 2-group of order $2^9$ generated by $g_1, g_2, \ldots, g_9$. Let $H := \langle g_1, g_2, g_3, g_4, g_5, g_6 \rangle$ and $T = \langle g_7, g_8, g_9 \rangle$. Set $\theta = [T_1, T_2, T_3]$ with $T_1 = \{1, g_7\}$, $T_2 = \{1, g_8\}$, $T_3 = \{1, g_9\}$. Define
\[ L_1 = \{ A_{1,1} = \{1, g_1, g_2, g_1g_2\}, A_{1,2} = \{1, g_1g_3, g_2g_4, g_1g_3g_2g_4\} \}, \]
\[ L_2 = \{ A_{2,1} = \{1, g_3, g_4, g_3g_4\}, A_{2,2} = \{1, g_1g_2g_3, g_1g_4, g_2g_3g_4\} \}, \]
\[ L_3 = \{ A_{3,1} = \{1, g_5, g_6, g_5g_6\}, A_{3,2} = \{1, g_1g_3g_5, g_2g_4g_6, g_1g_2g_3g_4g_5g_6\} \}. \]

It can be checked that each of the eight combinations $[A_{1,j_1}, A_{2,j_2}, A_{3,j_3}]$ with $j_1, j_2, j_3 \in \{1, 2\}$ forms a logarithmic signature for $H$. We thus obtain an aperiodic logarithmic signature $\beta = [B_1, B_2, B_3]$ of type $(8, 8, 8)$ with
\[ B_1 = \{1, g_1, g_2, g_1g_2, g_7, g_1g_3g_7, g_2g_4g_7, g_1g_3g_2g_4g_7\}, \]
\[ B_2 = \{1, g_3, g_4, g_3g_4, g_8, g_1g_2g_3g_8, g_1g_4g_8, g_2g_3g_4g_8\}, \]
\[ B_3 = \{1, g_5, g_6, g_5g_6, g_9, g_1g_3g_5g_9, g_2g_4g_5g_9, g_1g_2g_3g_4g_5g_9\}. \]

The aperiodicity of $\beta$ follows from Proposition 1, since $A_{i,1} \cap A_{i,2} = \{1\}$ for all $i = 1, 2, 3$.

An important property of logarithmic signatures constructed by the Baumeister-de Wiljes method is that they are tame when certain conditions are satisfied, see [1], [4]. The result is given by the following theorem.
**Theorem 1** Let $\beta := [B_1, \ldots, B_s]$ be a logarithmic signature constructed by the Baumeister-de Wiljes method. Assume that $\theta$ and all logarithmic signatures $[A_{1,j_1}, \ldots, A_{s,j_s}]$, $1 \leq j_i \leq r_i$ and $1 \leq i \leq s$, are tame. If $\theta$ and $L_1, \ldots, L_s$ are known, then $\beta$ is tame.

**Proof.** Let $g \in G$ be an element that we want to factorize with respect to $\beta$. Then there exist unique elements $t \in T$ and $h \in H$ such that $g = ht$. Since $\theta$ is tame, we can find a factorization of $t = t_{1,j_1} \cdots t_{s,j_s}$ with respect to $\theta$ in time bounded by $O(w^{c_1})$, where $w = \lceil \log |G| \rceil$ and $c_1$ is a constant. Having obtained $(j_1, \ldots, j_s)$ we can determine the logarithmic signature $[A_{1,j_1}, \ldots, A_{s,j_s}]$ which is tame by the assumption. So, the complexity of factoring $h = a_{1,k_1} \cdots a_{s,k_s}$ with respect to $[A_{1,j_1}, \ldots, A_{s,j_s}]$ is bounded by $O(w^{c_2})$, where $c_2$ is a constant. Thus

$$g = ht = a_{1,k_1} \cdots a_{s,k_s} t_{1,j_1} \cdots t_{s,j_s} = \left( a_{1,k_1} t_{1,j_1} \right) \cdots \left( a_{s,k_s} t_{s,j_s} \right).$$

Since, finding $a_{i,k_i} t_{i,j_i} \in B_i$ only requires a time of $O(\log_2(|B_i|))$ when $B_i$ is sorted. It follows that $\beta$ is tame. □

---

6 Strongly aperiodic logarithmic signatures for abelian groups

Within the class $\mathcal{A}(G)$ of aperiodic logarithmic signatures, we are interested in a subclass called strongly aperiodic logarithmic signatures, which we denote by $SA(G)$.

A simple observation shows that aperiodicity property of a logarithmic signature is preserved under the transformations described above, except the fusion. For fusing two or more blocks of an aperiodic logarithmic signature may result in a periodic logarithmic signature. Observe that if we fuse all the blocks of a logarithmic signature $\beta$, we obtain one block, namely the group $G$ itself, which is in turn a trivial periodic logarithmic signature. We will exclude this trivial case. Thus a fusion can be done on any set of at most $s - 1$ blocks of $\beta$. In general, we might expect that any nontrivial fusion is permitted, however it is not always so as we can see from following results as shown in the book of Szabó [13] for abelian p-groups.

**Theorem 2** Let $p$ be a prime and let $G$ be an abelian group of order $p^n$. Further let $r_1 \geq r_2 \geq \cdots \geq r_s \geq p$ be powers of $p$ such that

$$\prod_{i=1}^{s} r_i = p^n.$$

(i) ([13], Theorem 7.3.1) Suppose $p = 2$ and $G$ is an elementary abelian 2-group. A logarithmic signature $\alpha$ of type $(r_1, \ldots, r_s)$ with $r_1 \geq \cdots \geq r_s \geq 2$ can only be aperiodic if we have

- $s = 2$ and $r_2 \geq 8$, or
- $s \geq 3$ and $r_1 \geq 8$, $r_2 \geq \cdots \geq r_s \geq 4$.

$\alpha$ is always periodic for each of the following cases.

- $r_s = 2$, 

7
We use the setup for Example 2 logarithmic signature in this case. It seems not meaningful to extend the definition of a non-abelian group. This is because a fusion of non-consecutive blocks is almost prohibited, since the result is no longer a logarithmic signature in this case.

Remark 6.1

Definition 6.2 Let $\mathcal{G}$ be an abelian group and let $\beta = [B_1, \ldots, B_s] \in \mathcal{A}(\mathcal{G})$. The logarithmic signature $\beta$ is called strongly aperiodic if it achieves its admissible fusion degrees.
\[ L_1 = \{ A_{1,1} = \{1, g_1, g_2, g_1 g_2\}, A_{1,2} = \{1, g_1 g_2 g_3 g_6, g_2 g_3 g_5, g_1 g_3 g_4 g_5 g_6\} \}, \]
\[ L_2 = \{ A_{2,1} = \{1, g_3, g_4, g_3 g_4\}, A_{2,2} = \{1, g_1 g_3, g_2 g_4, g_3 g_2 g_4\} \}, \]
\[ L_3 = \{ A_{3,1} = \{1, g_5, g_6, g_5 g_6\}, A_{3,2} = \{1, g_1 g_5, g_2 g_6, g_1 g_5 g_2 g_6\} \}. \]

Then we obtain an aperiodic logarithmic signature \( \beta = [B_1, B_2, B_3] \) of type \( (8, 8, 8) \) for \( G \) with
\[ B_1 = \{1, g_1, g_2, g_1 g_2, g_1 g_2 g_7, g_1 g_2 g_4 g_6 g_7, g_1 g_2 g_4 g_6 g_7, g_1 g_3 g_4 g_5 g_6 g_7\}, \]
\[ B_2 = \{1, g_3, g_4, g_3 g_4, g_8, g_1 g_3 g_8, g_2 g_4 g_8, g_1 g_3 g_2 g_4 g_8\}, \]
\[ B_3 = \{1, g_5, g_6, g_5 g_6, g_9, g_1 g_5 g_9, g_2 g_6 g_9, g_1 g_5 g_2 g_6 g_9\}. \]

Now, it can be checked that the fusion of any two blocks of \( \beta \) yields an aperiodic block. Hence \( \beta \) is strongly aperiodic.

**Remark 6.2** We note that the logarithmic signature \( \beta \) in Example 1 is aperiodic but not strongly aperiodic. For, when fusing \( B_1 \) with \( B_2 \) we obtain a periodic block. Even more, \( B_1 B_2 \) is a subgroup of order \( 2^6 \) in \( G \).

As we will use the Baumeister-de Wiljes construction, denoted by BW-construction for short, to investigate strongly aperiodic logarithmic signatures, we make use of the following simple observation about the fusion operation on a logarithmic signature obtained from the BW-construction.

**Lemma 1** We use the notation as described in the BW-construction above. The fusion of blocks \( B_i \) and \( B_j \), \( i \neq j \), of \( \beta \) results in a logarithmic signature, which is again derived from the BW-construction, in which \( L_i \) and \( L_j \) are replaced by \( L_i L_j \) and \( T_i \) and \( T_j \) by \( T_i T_j \).

The next lemma is useful for the query about the strong aperiodicity of a logarithmic signature.

**Lemma 2** Let \( G \) be an abelian group. Let \( \beta = [B_1, \ldots, B_s] \) be a logarithmic signature for \( G \). Let \( I \subseteq \{1, \ldots, s\} \). Suppose that the fused block \( \prod_{i \in I} B_i \) is aperiodic. Then \( \prod_{j \in I} B_j \) is aperiodic for any non-empty subset \( J \subseteq I \).

**Proof.** Recall that element shuffle does not effect periodicity. Assume, by contradiction, that \( B_I := \prod_{j \in I} B_j \) is periodic for a subset \( J \subseteq I \). Let \( g \in G \setminus \{1\} \) be a period for \( B_J \). Set \( B_I := \prod_{i \in I} B_i \). We may write \( B_I = B_J \cdot C \), where \( C := \prod_{k \in I \setminus J} B_k \) (note that \( B_I \) on the left side of equality \( B_I = B_J \cdot C \) is considered as an unordered set, since permuting the elements of \( B_I \) does not effect the property of aperiodicity). Now, since \( g \) is a period for \( B_J \) we have \( g B_I = g B_J \cdot C = B_J \cdot C = B_I \). Thus \( g \) is a period for \( B_I \), a contradiction. \( \square \)

Lemma 2 is a crucial tool. Suppose we want to verify the strong aperiodicity of a logarithmic signature \( \beta \) having \( s \) blocks. Suppose further that we are allowed to fuse up to any \( s - 1 \) blocks of \( \beta \). Without Lemma 2 we have to check all \( \binom{s}{1} + \binom{s}{2} + \cdots + \binom{s}{s-1} = 2^s - 2 \) possible fusions of the blocks of \( \beta \). Whereas by using Lemma 2 we only need to check \( \binom{s}{s-1} = s \) fusions of all combinations of \( s - 1 \) blocks of \( \beta \).
In the remaining sections we present constructions of strongly aperiodic signatures for elementary abelian \( p \)-groups. The basic tool we use is the BW-construction. We first construct certain types of aperiodic logarithmic signatures, and then in a further more involved step we prove that they are strongly aperiodic.

From now on let \( G \) be an elementary abelian \( p \)-group. We use additive notation for the group operation and \( 0 \) will denote the identity of \( G \). In fact we identify \( G \) with the additive group of the Galois field \( \mathbb{F}_p^n \). In this way \( G \) is viewed as a vector space of dimension \( n \) over \( \mathbb{F}_p \), and thus we may freely use the language of linear algebra with respect to \( G \). For example, a minimal generator set for \( G \) may be called a basis for \( G \).

7 Strongly aperiodic logarithmic signatures of type \( (p^3, \ldots, p^3) \)

In this section we first construct a strongly aperiodic logarithmic signature of type \( (p^3, \ldots, p^3) \) for an elementary abelian \( p \)-group \( G \) of order \( p^{3s} \), where \( p = 2 \) or \( p \) is an odd prime and \( s \geq 2 \). Let \( v_1, v_2, \ldots, v_{2s}, \ldots, v_{3s} \) be a generator set of \( G \). Using the BW-construction we define

(i) \( T = \langle v_{2s+1}, \ldots, v_{3s} \rangle \) and \( \theta = [T_1, \ldots, T_s] \) with

\[
T_i = \{0, v_{2s+i}, 2v_{2s+i}, \ldots, (p-1)v_{2s+i}\} \quad \text{for } i = 1, \ldots, s,
\]

(ii) \( H = \langle v_1, \ldots, v_{2s} \rangle \).

Let \( u \in \{1, \ldots, p-1\} = \mathbb{F}_p \setminus \{0\} \) be a chosen parameter. For \( i = 1, \ldots, s \) define collection

\[
L_i = \{A_{i,0}, A_{i,1}, \ldots, A_{i,(p-1)}\}
\]
as follows.

\[
A_{1,0} = \langle v_1, v_2 \rangle, \quad A_{1,j} = \langle v_1 + v_2 + j \cdot \sum_{\ell=2}^{s} v_{2\ell}, u \cdot v_2 + j \cdot \sum_{\ell=2}^{s} v_{2\ell-1} \rangle \quad \text{for all } j \in \{1, \ldots, p-1\},
\]

\[
A_{i,j} = \langle v_{2i-1} + jv_1, v_{2i} + jv_2 \rangle \quad \text{for all } i \in \{2, \ldots, s\}, j \in \{0, \ldots, p-1\}.
\]

Remark 7.1 Note that in (i) we may replace \( T \) by any transversal \( TR \) of \( H \). Here \( TR \) is not a subgroup in general. In fact, it is simple to create a logarithmic signature for a transversal of \( H \) by passing to the quotient group \( \overline{T} = G/H \). Namely, let \( \theta = [\overline{T}_1, \ldots, \overline{T}_s] \) be a logarithmic signature for \( T \), where \( \overline{T}_i = [x_{i,0}H, \ldots, x_{i,(p-1)}H, 1 \leq i \leq s] \) be a logarithmic signature for \( \overline{T} \), where \( \overline{T}_i = [x_{i,0}, \ldots, x_{i,(p-1)}] \) for a certain transversal \( TR \) of \( H \).

We now prove that the subsets \( A_{i,j} \) of \( L_i \), \( 1 \leq i \leq s \) satisfy condition (ii) of the BW-construction. This means that for any \( (j_1, j_2, \ldots, j_s) \in \{0, 1, \ldots, p-1\}^s \) the collection \( [A_{1,j_1}, A_{2,j_2}, \ldots, A_{s,j_s}] \) forms
a logarithmic signature for $\mathcal{H}$. This is equivalent to say that the basis elements of $A_{1,j_1}, A_{2,j_2}, \ldots, A_{s,j_s}$ are linearly independent.

We first consider the case $j_1 = 0$.

We then have $A_{1,j_1} = \langle v_1, v_2 \rangle$, $A_{2,j_2} = \langle j_2 \cdot v_1 + v_3, j_2 \cdot v_2 + v_4 \rangle$, $A_{3,j_3} = \langle j_3 \cdot v_1 + v_5, j_3 \cdot v_2 + v_6 \rangle$, ..., $A_{s,j_s} = \langle j_s \cdot v_1 + v_{2s-1}, j_s \cdot v_2 + v_{2s} \rangle$. When forming a linear combination of the basis elements of $A_{1,0, A_{2,j_2}, \ldots, A_{s,j_s}}$ for the zero element we have

$$0 = \lambda_{1,1} \cdot (v_1) + \lambda_{1,2} \cdot (v_2) + \lambda_{2,1} \cdot (v_{2i-1} + j_2 v_1) + \lambda_{2,2} \cdot (v_{2i} + j_2 v_2) + \cdots + \lambda_{s,1} \cdot (v_{2s-1} + j_s v_1) + \lambda_{s,2} \cdot (v_{2s} + j_s v_2)$$

with $\lambda_{i,j} \in \mathbb{F}_p$. The matrix form of equation 7.2 is given by

$$(\lambda_{1,1}, \lambda_{1,2}, \ldots, \lambda_{s,1}, \lambda_{s,2}) M = (0, 0, \ldots, 0),$$

where $M$ is the following $(2s \times 2s)$-matrix over $\mathbb{F}_p$

$$M = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
j_2 & 0 & 1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & j_2 & 0 & 1 & 0 & 0 & \cdots & 0 & 0 & 0 \\
j_3 & 0 & 0 & 0 & 1 & 0 & \cdots & 0 & 0 & 0 \\
0 & j_3 & 0 & 0 & 0 & 1 & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
j_s & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 1 & 0 \\
0 & j_s & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 1
\end{pmatrix}$$

As $M$ is a lower triangular matrix with all 1 on the main diagonal, $M$ is invertible and equation 7.2 has $\lambda_{i,j} = 0$ for all $1 \leq i \leq s$ and $1 \leq j \leq 2s$ as the unique solution. Thus the basis elements of $A_{1,0, A_{2,j_2}, \ldots, A_{s,j_s}}$ are linearly independent. This says, in particular, that $[A_{1,0, A_{2,j_2}, \ldots, A_{s,j_s}}]$ forms a logarithmic signature for $\mathcal{H}$.

We now consider the case $j_1 \neq 0$.

We then have

$$A_{1,j_1} = \langle v_1 + v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell}, u \cdot v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell-1} \rangle,$$

$$A_{2,j_2} = \langle j_2 \cdot v_1 + v_3, j_2 \cdot v_2 + v_4 \rangle, A_{3,j_3} = \langle j_3 \cdot v_1 + v_5, j_3 \cdot v_2 + v_6 \rangle, \ldots$$

$$A_{s,j_s} = \langle j_s \cdot v_1 + v_{2s-1}, j_s \cdot v_2 + v_{2s} \rangle$$

and we obtain a linear combination of the zero element as follows:

$$0 = \lambda_{1,1} \cdot (v_1 + v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell}) + \lambda_{1,2} \cdot (u \cdot v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell-1}) + \lambda_{2,1} \cdot (v_{2i-1} + j_2 v_1) + \lambda_{2,2} \cdot (v_{2i} + j_2 v_2) + \cdots + \lambda_{s,1} \cdot (v_{2s-1} + j_s v_1) + \lambda_{s,2} \cdot (v_{2s} + j_s v_2)$$

(7.3)
The coefficient matrix $M$ of equation 7.3 has the form

$$
M = \begin{pmatrix}
1 & 1 & 0 & j_1 & 0 & j_1 & \ldots & j_1 & 0 & j_1 \\
0 & u & j_1 & 0 & j_1 & 0 & \ldots & 0 & j_1 & 0 \\
j_2 & 0 & 1 & 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\
0 & j_2 & 0 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 \\
j_3 & 0 & 0 & 0 & 1 & 0 & \ldots & 0 & 0 & 0 \\
0 & j_3 & 0 & 0 & 0 & 1 & \ldots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
j_s & 0 & 0 & 0 & 0 & 0 & \ldots & 0 & 1 & 0 \\
0 & j_s & 0 & 0 & 0 & 0 & \ldots & 0 & 0 & 1 \\
\end{pmatrix}
$$

By subtracting $j_1$ times the rows 4, 6, \ldots, $2s$ from the first row, and $j_1$ times the rows 3, 5, \ldots, $2s-1$ from the second row of $M$ we obtain the following matrix

$$
\begin{pmatrix}
1 & 1 - j_1 \cdot \sum_{i=2}^{s} j_i & u & 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\
-j_1 \cdot \sum_{i=2}^{s} j_i & u & 0 & 0 & 0 & \ldots & 0 & 0 & 0 \\
j_2 & 0 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 \\
0 & j_2 & 0 & 1 & 0 & \ldots & 0 & 0 & 0 \\
j_3 & 0 & 0 & 0 & 1 & \ldots & 0 & 0 & 0 \\
0 & j_3 & 0 & 0 & 0 & 1 & \ldots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
j_s & 0 & 0 & 0 & 0 & 0 & \ldots & 0 & 1 & 0 \\
0 & j_s & 0 & 0 & 0 & 0 & \ldots & 0 & 0 & 1 \\
\end{pmatrix}
$$

with determinant $u + (1 - J)J = -(J^2 - J - u)$ where $J := j_1 \cdot \sum_{i=2}^{s} j_i$. Since for each given $p$ we can choose a $u \in \mathbb{F}_p \setminus \{0\}$ such that the polynomial $X^2 - X - u \in \mathbb{F}_p[X]$ has no root in $\mathbb{F}_p$, we can conclude that matrix $M$ is invertible and therefore equation 7.3 has a unique solution with $\lambda_{i,j} = 0$ for all $1 \leq i \leq s$ and $1 \leq j \leq 2$. So the basis elements of $A_{1,j_1}, A_{2,j_2}, \ldots, A_{s,j_s}$ are linearly independent. Hence $[A_{1,j_1}, A_{2,j_2}, \ldots, A_{s,j_s}]$ forms a logarithmic signature for $\mathcal{H}$.

Thus we have constructed a logarithmic signature $\beta$ of type $(p^3, \ldots, p^3)$ for $\mathcal{G}$ by the method of Baumeister and de Wiljes. By using Proposition 1 and the fact that $A_{i,j} \cap A_{i,k} = \{0\}$ for any $A_{i,j}, A_{i,k} \in \mathcal{L}_i$ with $j \neq k$ and for all $1 \leq i \leq s$, we conclude that $\beta$ is aperiodic.

The strong aperiodicity of $\beta$ will be proved by the following theorem.

**Theorem 3** The above constructed logarithmic signature $\beta$ of type $(p^3, \ldots, p^3)$ is strongly aperiodic.

**Proof.** Recall that Lemma 1 says that fusing any two blocks of $\beta$ results in a logarithmic signature, which is again obtained from the BW-construction. By using Lemma 2 we need only to consider the fusion of any $(s-1)$ blocks of $\beta$. Finally, we use Proposition 1 to show that the resulting logarithmic signature derived from each such fusion is aperiodic. This is done by showing that the fusion of any $(s-1)$ collections $\mathcal{L}_i$ yields a collection of subgroups of $\mathcal{G}$ having only the identity element 0 of $\mathcal{G}$ in their intersection.
We consider three cases.

**Case 1:** Fusing $\mathcal{L}_2, \ldots, \mathcal{L}_s$.

Let denote $\mathcal{L}_2 + \cdots + \mathcal{L}_s$ the collection obtained by fusing $\mathcal{L}_2, \ldots, \mathcal{L}_s$. The subsets of $\mathcal{L}_2 + \cdots + \mathcal{L}_s$ are of the form $(A_{2,j_2} + A_{3,j_3} + \cdots + A_{s,j_s})$ with $(j_2, j_3, \ldots, j_s) \in \{0, 1, \ldots, p-1\}^{s-1}$.

We now prove that

$$
\forall (j_2, j_3, \ldots, j_s) \in \{0, 1, \ldots, p-1\}^{s-1}
$$

$$(A_{2,j_2} + A_{3,j_3} + \cdots + A_{s,j_s}) = \{0\}.
$$

Observe that

$$(A_{2,0} + A_{3,0} + \cdots + A_{s,0}) \cap (A_{2,1} + A_{3,0} + \cdots + A_{s,0}) = \langle v_3, v_4, v_5, v_6, \ldots, v_{2s-1}, v_{2s} \rangle \cap \langle v_1 + v_3, v_2 + v_4, v_5, v_6, \ldots, v_{2s-1}, v_{2s} \rangle = \langle v_5, v_6, \ldots, v_{2s-1}, v_{2s} \rangle = A_{3,0} + A_{4,0} + \cdots + A_{s,0}.
$$

Similarly, we have

$$(A_{2,0} + A_{3,0} + A_{4,0} + \cdots + A_{s,0}) \cap (A_{2,0} + A_{3,1} + A_{4,0} + \cdots + A_{s,0}) = A_{2,0} + A_{4,0} + \cdots + A_{s,0}, \ldots,$$

$$(A_{2,0} + \cdots + A_{s-1,0} + A_{s,0}) \cap (A_{2,0} + \cdots + A_{s-2,0} + A_{s-1,1} + A_{s,0}) = A_{2,0} + A_{3,0} + \cdots + A_{s-2,0} + A_{s,0},$$

$$(A_{2,0} + \cdots + A_{s-1,0} + A_{s,0}) \cap (A_{2,0} + A_{3,0} + \cdots + A_{s-1,0} + A_{s,1}) = A_{2,0} + A_{3,0} + \cdots + A_{s-1,0}.$$

Obviously, the intersection of the elements on the right hand side of the equalities is trivial.

**Case 2:** Fusing $\mathcal{L}_1, \mathcal{L}_2, \ldots, \mathcal{L}_{s-1}$.

We prove that

$$
\forall (j_1, j_2, \ldots, j_{s-1}) \in \{0, 1, \ldots, p-1\}^{s-1}
$$

$$(A_{1,j_1} + A_{2,j_2} + \cdots + A_{s-1,j_{s-1}}) = \{0\}.
$$

Recall that

$$A_{1,0} = \langle v_1, v_2 \rangle, \ A_{1,j} = \langle v_1 + v_2 + j \cdot \sum_{\ell=2}^{s} v_{2\ell}, \ u \cdot v_2 + j \cdot \sum_{\ell=2}^{s} v_{2\ell-1} \rangle,
$$

$j \in \{1, \ldots, p-1\},$

$$A_{i,j} = \langle v_{2i-1} + jv_1, \ v_{2i} + jv_2 \rangle, \ i \in \{2, \ldots, s\}, \ j \in \{0, \ldots, p-1\}.$$

13
So we have
\[(A_{1,0} + A_{2,0} + \cdots + A_{s-1,0}) \cap (A_{1,1} + A_{2,0} + \cdots + A_{s-1,0}) =
\langle v_1, v_2, v_3, v_4, \ldots, v_{2s-3}, v_{2s-2} \rangle \cap \langle v_1 + v_2 + \sum_{\ell=2}^{s} v_{2\ell}, u \cdot v_2 + \sum_{\ell=2}^{s} v_{2\ell-1},
v_3, v_4, \ldots, v_{2s-3}, v_{2s-2} \rangle =
A_{2,0} + A_{3,0} + \cdots + A_{s-1,0}.
\]

Consider further intersection:
\[(A_{2,0} + A_{3,0} + \cdots + A_{s-1,0}) \cap (A_{1,1} + A_{2,1} + A_{3,0} + \cdots + A_{s-1,0}) =
\langle v_3, v_4, v_5, \ldots, v_{2s-3}, v_{2s-2} \rangle \cap \langle v_3 + v_4 + v_2, v_5, \ldots, v_{2s-3}, v_{2s-2} \rangle =
\langle v_5, v_6, \ldots, v_{2s-3}, v_{2s-2} \rangle = (A_{3,0} + \cdots + A_{s-1,0}).
\]

Similarly,
\[(A_{3,0} + \cdots + A_{s-1,0}) \cap (A_{1,1} + A_{2,0} + A_{3,1} + A_{4,0} + \cdots + A_{s-1,0}) =
\langle v_5, v_6, \ldots, v_{2s-3}, v_{2s-2} \rangle \cap \langle v_5, v_4 + v_5 + v_6 + v_2, v_7, \ldots, v_{2s-3}, v_{2s-2} \rangle =
\langle v_7, v_8, \ldots, v_{2s-3}, v_{2s-2} \rangle = A_{4,0} + \cdots + A_{s-1,0}
\]
This process can be iterated until we get \(\{0\}\) as the intersection.

**Case 3:** Fusing \(L_1, \ldots, L_{k-1}, L_{k+1}, \ldots, L_{s-1}, L_s\) for all \(k \in \{2, 3, \ldots, s-2, s-1\}\).

We claim that
\[
\bigcap_{\forall (j_1, \ldots, j_{k-1},
\ j_{k+1}, \ldots, j_s) \in \{0,1,\ldots,p-1\}^{s-1}} (A_{1,j_1} + \cdots + A_{k-1,j_{k-1}} + A_{k+1,j_{k+1}} + \cdots + A_{s,j_s}) = \{0\}.
\]

We define an isomomorphism \(\Phi\) of \(G\) as follows
\[
\Phi(v_i) =
\begin{cases}
  v_{2s-1} & \text{if } i = 2k - 1 \\
  v_{2k-1} & \text{if } i = 2s - 1 \\
  v_{2s} & \text{if } i = 2k \\
  v_{2k} & \text{if } i = 2s \\
  v_i & \text{otherwise}
\end{cases}
\]

Thus \(\Phi\) interchanges \(v_{2k-1}\) with \(v_{2s-1}\) and \(v_{2k}\) with \(v_{2s}\), and fixes the remaining generators. Then we have
\[
\Phi (A_{1,j_1}) = \Phi \left( \langle v_1 + v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell}, u \cdot v_2 + j_1 \sum_{\ell=2}^{s} v_{2\ell-1} \rangle \right) = A_{1,j_1},
\]

14
\[ \Phi(A_{2,j_2}) = \Phi\left(\langle j_2 \cdot v_1 + v_3, j_2 \cdot v_2 + v_4 \rangle\right) = A_{2,j_2}, \ldots, \]
\[ \Phi(A_{k-1,j_{k-1}}) = \Phi\left(\langle j_{k-1} \cdot v_1 + v_{2(k-1)-1}, j_2 \cdot v_2 + v_{2(k-1)} \rangle\right) = A_{k-1,j_{k-1}}, \]
\[ \Phi(A_{k,j_k}) = \Phi\left(\langle j_k \cdot v_1 + v_{2k-1}, j_k \cdot v_2 + v_{2k} \rangle\right) = A_{s,j_k}, \]
\[ \Phi(A_{k+1,j_{k+1}}) = \Phi\left(\langle j_{k+1} \cdot v_1 + v_{2(k+1)-1}, j_2 \cdot v_2 + v_{2(k+1)} \rangle\right) = A_{k+1,j_{k+1}}, \ldots, \]
\[ \Phi(A_{s-1,j_{s-1}}) = \Phi\left(\langle j_{s-1} \cdot v_1 + v_{2(s-1)-1}, j_2 \cdot v_2 + v_{2(s-1)} \rangle\right) = A_{s-1,j_{s-1}}, \]
\[ \Phi(A_{s,j_s}) = \Phi\left(\langle j_s \cdot v_1 + v_{2s-1}, j_s \cdot v_2 + v_{2s} \rangle\right) = A_{k,j_s}. \]

From
\[ \bigcap_{\forall (j_1,j_2,\ldots,j_{s-1}) \in \{0,1,\ldots,p-1\}^{s-1}} (A_{1,j_1} + A_{2,j_2} + \cdots + A_{s-1,j_{s-1}}) = \{0\} \]
we conclude that
\[ \bigcap_{\forall (j_1,j_2,\ldots,j_{s-1}) \in \{0,1,\ldots,p-1\}^{s-1}} (\Phi(A_{1,j_1}) + \Phi(A_{2,j_2}) + \cdots + \Phi(A_{s-1,j_{s-1}})) = \{0\} \]

This implies that
\[ \bigcap_{\forall (j_1,j_2,\ldots,j_{s-1}) \in \{0,1,\ldots,p-1\}^{s-1}} \left( A_{1,j_1} + \cdots + A_{k-1,j_{k-1}} + \Phi(A_{k,j_k}) + A_{k+1,j_{k+1}} + \cdots + A_{s-1,j_{s-1}} \right) = \{0\}. \]

So we have
\[ \bigcap_{\forall (j_1,j_2,\ldots,j_{s-1}) \in \{0,1,\ldots,p-1\}^{s-1}} \left( A_{1,j_1} + \cdots + A_{k-1,j_{k-1}} + A_{s,j_s} + A_{k+1,j_{k+1}} + \cdots + A_{s-1,j_{s-1}} \right) = \{0\}, \]

which shows the claim. This completes the proof. □

**Remark 7.2** The strongly aperiodic logarithmic signature \( \beta \) of type \((8,8,8)\) in Example 2 above is constructed by the method in this section.

## 8 Strongly aperiodic logarithmic signatures of type \((2^3, 2^2, \ldots, 2^2)\)

In this section we will construct strongly aperiodic logarithmic signatures of type \((2^3, 2^2, \ldots, 2^2)\) for an elementary abelian 2-group \( G \) of order \( 2^{2s-1} \) with \( s \geq 4 \). Let \( v_1, v_2, \ldots, v_{s}, v_{s+1}, \ldots, v_{2s-1} \) be a generator set of \( G \). Using the BW-construction we define

(i) \( \mathcal{T} = \langle v_{s+1}, \ldots, v_{2s-1} \rangle \) and \( \theta = [T_1, T_3, T_4, \ldots, T_s] \) with \( T_1 = \{0, v_{s+1}\} \) and \( T_i = \{0, v_{s+(i-1)}\} \) for \( i = 3, 4, \ldots, 2s \),

15
(ii) $H = \langle v_1, \ldots, v_s \rangle$.

Note that for the reason of simplicity we have omitted $i = 2$ in indexing the collections $L_i$ and also the blocks $T_i$ so that we only have $s-1$ blocks.

For $i = 1, 3, 4, \ldots, s$ define collection

$$L_i = \{A_{i,0}, A_{i,1}\}$$

as follows

$$A_{1,0} = \langle v_1, v_2 \rangle, \quad A_{1,1} = \langle v_1 + \sum_{\ell=2}^{[s/2]} v_{2\ell-1}, v_2 + \sum_{\ell=2}^{[s/2]} v_{2\ell} \rangle,$$

and for $i = 3, \ldots, s$,

$$A_{i,0} = \langle v_i \rangle, \quad A_{i,1} = \langle v_i + \sum_{\ell=1}^{[i/2]} v_{2\ell} \rangle, \quad \text{if } i \text{ is odd},$$

$$A_{i,0} = \langle v_i \rangle, \quad A_{i,1} = \langle v_i + \sum_{\ell=1}^{i/2} v_{2\ell-1} \rangle, \quad \text{if } i \text{ is even}.$$

**Remark 8.1** In the same manner as Remark 7.1, we may choose $\theta$ as a logarithmic signature for a certain transversal $TR$ of $H$ in $G$.

At first we prove that for any choice of $(j_1, j_3, j_4, \ldots, j_s) \in \{0, 1\}^{s-1}$ the corresponding collection $[A_{1,j_1}, A_{3,j_3}, A_{4,j_4}, \ldots, A_{s,j_s}]$ forms a logarithmic signature for $H$. The is equivalent to show that the linear combination of the zero element of $G$ with respect to the basis elements of $A_{1,j_1}, A_{3,j_3}, A_{4,j_4}, \ldots, A_{s,j_s}$, i.e.

$$0 = \lambda_1 \cdot (v_1 + j_1 \sum_{\ell=2}^{[s/2]} v_{2\ell-1}) + \lambda_2 \cdot (v_2 + j_1 \sum_{\ell=2}^{[s/2]} v_{2\ell}) + \sum_{i=1}^{[(s-1)/2]} \lambda_{2i+1} \cdot (v_{2i+1} + j_{2i+1} \sum_{\ell=1}^{i} v_{2\ell}) + \sum_{i=2}^{[(s-1)/2]} \lambda_{2i} \cdot (v_{2i} + j_{2i} \sum_{\ell=1}^{i} v_{2\ell-1})$$

(8.4)

only has the trivial solution $\lambda_i = 0$ for all $i = 1, 3, \ldots, s$. This means that the $(s \times s)$ coefficient matrix $M_s(j_1, j_3, j_4, \ldots, j_s)$ for $\lambda_i$’s of equation 8.4 is invertible.

If $s$ is even, we have
\[
M_s(j_1, j_3, j_4, \ldots, j_s) = \\
\begin{pmatrix}
1 & 0 & j_1 & 0 & j_1 & 0 & \ldots & j_1 & 0 & j_1 & 0 \\
0 & 1 & 0 & j_1 & 0 & j_1 & \ldots & 0 & j_1 & 0 & j_1 \\
0 & j_3 & 1 & 0 & 0 & 0 & \ldots & 0 & 0 & 0 & 0 \\
j_4 & 0 & j_4 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 & 0 \\
0 & j_5 & 0 & j_5 & 1 & 0 & \ldots & 0 & 0 & 0 & 0 \\
j_6 & 0 & j_6 & 0 & j_6 & 1 & \ldots & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
0 & j_{s-3} & 0 & j_{s-3} & 0 & j_{s-3} & \ldots & 1 & 0 & 0 & 0 \\
j_{s-2} & 0 & j_{s-2} & 0 & j_{s-2} & 0 & \ldots & j_{s-2} & 1 & 0 & 0 \\
0 & j_{s-1} & 0 & j_{s-1} & 0 & j_{s-1} & \ldots & 0 & j_{s-1} & 1 & 0 \\
j_s & 0 & j_s & 0 & j_s & 0 & \ldots & j_s & 0 & j_s & 1 \\
\end{pmatrix}
\]

If \( s \) is odd, we have
\[
M_s(j_1, j_3, j_4, \ldots, j_s) = \\
\begin{pmatrix}
1 & 0 & j_1 & 0 & j_1 & 0 & \ldots & j_1 & 0 & j_1 & 0 \\
0 & 1 & 0 & j_1 & 0 & j_1 & \ldots & 0 & j_1 & 0 & j_1 \\
0 & j_3 & 1 & 0 & 0 & 0 & \ldots & 0 & 0 & 0 & 0 \\
j_4 & 0 & j_4 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 & 0 \\
0 & j_5 & 0 & j_5 & 1 & 0 & \ldots & 0 & 0 & 0 & 0 \\
j_6 & 0 & j_6 & 0 & j_6 & 1 & \ldots & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
j_{s-3} & 0 & j_{s-3} & 0 & j_{s-3} & 0 & \ldots & 1 & 0 & 0 & 0 \\
j_{s-2} & 0 & j_{s-2} & 0 & j_{s-2} & 0 & \ldots & j_{s-2} & 1 & 0 & 0 \\
j_{s-1} & 0 & j_{s-1} & 0 & j_{s-1} & 0 & \ldots & 0 & j_{s-1} & 1 & 0 \\
j_s & 0 & j_s & 0 & j_s & 0 & \ldots & j_s & 0 & j_s & 1 \\
\end{pmatrix}
\]

In both cases the matrix is invertible if \( j_1 = 0 \). Hence we assume that \( j_1 = 1 \).

We show by induction on \( s \) that the determinant of \( M_s(j_1, j_3, j_4, \ldots, j_s) \) is 1 in both cases.

To begin with if \( s = 3 \) we have
\[
\det (M_3(j_1, j_3)) = \det \begin{pmatrix} 1 & 0 & j_1 \\ 0 & 1 & 0 \\ 0 & j_3 & 1 \end{pmatrix} = 1.
\]

Now, let \( s > 3 \).

If \( s \) is even, we subtract \( j_s \) times the first row from the last row and obtain
\[
\det (M_s(j_1, j_3, j_4, \ldots, j_s)) =
\begin{pmatrix}
1 & 0 & j_1 & 0 & j_1 & 0 & \cdots & j_1 & 0 & j_1 & 0 \\
0 & 1 & 0 & j_1 & 0 & j_1 & \cdots & 0 & j_1 & 0 & j_1 \\
0 & j_4 & 1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
0 & j_5 & 0 & j_5 & 1 & 0 & \cdots & 0 & 0 & 0 & 0 \\
j_6 & 0 & j_6 & 0 & j_6 & 1 & \cdots & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
0 & j_{s-3} & 0 & j_{s-3} & 0 & j_{s-3} & \cdots & 1 & 0 & 0 & 0 \\
j_{s-2} & 0 & j_{s-2} & 0 & j_{s-2} & 0 & \cdots & j_{s-2} & 1 & 0 & 0 \\
j_s & 0 & j_{s-1} & 0 & j_{s-1} & 0 & j_{s-1} & \cdots & 0 & j_{s-1} & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 1 \\
\end{pmatrix}
\]

= \det (M_{s-1}(j_1, j_3, j_4, \ldots, j_{s-1})).

If \(s\) is odd, we subtract \(j_s\) times the second row from the last row and obtain

\[
\det (M_s(j_1, j_3, j_4, \ldots, j_s)) =
\begin{pmatrix}
1 & 0 & j_1 & 0 & j_1 & 0 & \cdots & 0 & j_1 & 0 & j_1 \\
0 & 1 & 0 & j_1 & 0 & j_1 & \cdots & 0 & j_1 & 0 & j_1 \\
0 & j_3 & 1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
0 & j_4 & 0 & j_4 & 1 & 0 & \cdots & 0 & 0 & 0 & 0 \\
0 & j_5 & 0 & j_5 & 1 & 0 & \cdots & 0 & 0 & 0 & 0 \\
j_6 & 0 & j_6 & 0 & j_6 & 1 & \cdots & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
0 & j_{s-3} & 0 & j_{s-3} & 0 & j_{s-3} & \cdots & 1 & 0 & 0 & 0 \\
j_{s-2} & 0 & j_{s-2} & 0 & j_{s-2} & 0 & \cdots & j_{s-2} & 1 & 0 & 0 \\
j_s & 0 & j_{s-1} & 0 & j_{s-1} & 0 & j_{s-1} & \cdots & 0 & j_{s-1} & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 1 \\
\end{pmatrix}
\]
\[
\begin{pmatrix}
1 & 0 & j_1 & 0 & j_1 & 0 & \cdots & 0 & j_1 & 0 \\
0 & 1 & 0 & j_1 & 0 & j_1 & \cdots & j_1 & 0 & j_1 \\
0 & j_3 & 1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
j_4 & 0 & j_4 & 1 & 0 & 0 & \cdots & 0 & 0 & 0 \\
j_5 & 0 & j_5 & 0 & j_5 & 1 & 0 & \cdots & 0 & 0 \\
j_6 & 0 & j_6 & 0 & j_6 & 1 & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
j_{s-3} & 0 & j_{s-3} & 0 & j_{s-3} & 0 & \cdots & 1 & 0 & 0 \\
j_{s-2} & 0 & j_{s-2} & 0 & j_{s-2} & \cdots & j_{s-2} & 1 & 0 & j_{s-1} \\
j_{s-1} & 0 & j_{s-1} & 0 & j_{s-1} & 0 & \cdots & 0 & 0 & j_{s-1} & 1
\end{pmatrix}
= \det (M_{s-1}(j_1, j_3, j_4, \ldots, j_{s-1})).
\]

In both cases induction shows us that the determinant is 1. Hence \([A_{1,j_1}, A_{3,j_3}, \ldots, A_{s,j_s}]\) forms a logarithmic signature for \(H\).

Thus we have constructed a logarithmic signature \(\beta\) of type \((2^3, 2^2, \ldots, 2^2)\) for \(G\) from the method of Baumeister and de Wiljes. By using Proposition 1 and the fact that \(A_{i,1} \cap A_{i,2} = \{0\}\) for any \(i = 1, 3, 4, \ldots, s\), we conclude that \(\beta\) is aperiodic.

Next we prove the following theorem.

**Theorem 4** The above constructed logarithmic signature \(\beta\) of type \((2^3, 2^2, \ldots, 2^2)\) is strongly aperiodic.

The proof of the strong aperiodicity for \(\beta\) is given by a number of lemmas.

In view of Theorem 2, we have to consider two types of fusions for \(\beta\): (a) fusing all \((s - 1)\) blocks of size \(2^2\) each (b) fusing any \((s - 2)\) blocks, where one block is of size \(2^3\). By Lemmas 1, 2 and Proposition 1 we have to show that for type (a) fusion of \(L_3, L_4, \ldots, L_s\) and for type (b) fusion of \(L_1\) with any \((s - 3)\) other collections \(L_i\) each yields a collection of subgroups of \(G\) having only the identity element 0 in their intersection.

**Case (a):** Fusing \(L_3, L_4, \ldots, L_s\).

**Lemma 3**

\[
\bigcap_{\langle j_3, j_4, \ldots, j_{s-1}, j_s \rangle \in \{0,1\}^{s-2}} (A_{3,j_3} + A_{4,j_4} + \cdots + A_{s-1,j_{s-1}} + A_{s,j_s}) = \{0\}.
\]

**Proof.** We consider the following two sums

\[
A_{3,0} + A_{4,0} + A_{5,0} + \cdots + A_{s-2,0} + A_{s-1,0} + A_{s,0} = \langle v_3, v_4, \ldots, v_{s-1}, v_s \rangle,
\]

and

\[
[A_{3,0} + A_{4,0} + A_{5,0} + \cdots + A_{s-2,0} + A_{s-1,0} + A_{s,1} =
\]

19
\[ \langle v_3, v_4, \ldots, v_{s-2}, v_{s-1}, v_s + v_{s-1} + v_{s-3} + \cdots \rangle. \]

Their intersection is
\[ \langle v_3, v_4, \ldots, v_{s-2}, v_{s-1} \rangle, \]
because either \( v_1 \) or \( v_2 \) occurs as a summand in the last term of the second sum.

When intersecting \( \langle v_3, v_4, \ldots, v_{s-2}, v_{s-1} \rangle \) further with the sum
\[ A_{3,0} + A_{4,0} + A_{5,0} + \cdots + A_{s-3,0} + A_{s-2,0} + A_{s-1,1} + A_{s,0} = \]
\[ \langle v_3, v_4, \ldots, v_{s-3}, v_{s-2}, v_s, (v_{s-1} + v_{s-2} + v_{s-4} + \cdots) \rangle \]
we obtain
\[ \langle v_3, v_4, \ldots, v_{s-3}, v_{s-2} \rangle, \]
as their intersection, because either \( v_1 \) or \( v_2 \) occurs as a summand in the last two terms of the sum.

By doing further iterations we eventually get \( \{0\} \) as intersection, as claimed. \( \square \)

**Case (b): Fusing \( \mathcal{L}_1 \) with \((s-3)\) other \( \mathcal{L}_i \)'s.**

Now, let \( I = \{i_1, \ldots, i_{s-3}\} \subseteq \{3, 4, \ldots, s\} \) be arbitrary with \( |I| = s-3 \). Let \( \{3, 4, \ldots, s\} \setminus I = \{k_1, k_2\} \), where we assume that \( k_1 < k_2 \).

We have to prove that
\[ \bigcap_{(j_1,j_2,j_3,\ldots) \in \{0,1\}^{s-3}} \left( \sum_{i \in I \cup \{1\}} A_{i,j_i} \right) = \{0\} \]

Here we have
\[ A_{1,0} + \sum_{i \in I} A_{j,0} = \]
\[ \langle v_1, v_2, v_4, \ldots, v_{k_1-1}, v_{k_1+1}, \ldots, v_{k_2-1}, v_{k_2+1}, \ldots, v_{i_s-3} \rangle. \]

There are three subcases which we have to handle separately.

(i) \( k_1 \equiv k_2 \equiv 1 \mod 2 \),
(ii) \( k_1 \equiv k_2 \equiv 0 \mod 2 \),
(iii) \( k_1 + k_2 \equiv 1 \mod 2 \).

**Lemma 4** Suppose that \( k_1 \equiv k_2 \equiv 1 \mod 2 \). Then equation (8.5) is satisfied.

**Proof.** First consider
\[ A_{1,1} + \sum_{i \in I} A_{i,0} = \]
\[ \langle v_1 + v_3 + v_5 + \cdots, v_2 + v_4 + v_6 + \cdots, v_{i_1}, v_{i_2}, \ldots, v_{k_1-1}, v_{k_1+1}, \ldots, v_{i_s-3} \rangle. \]
Since \( v_1 \notin A_{1,1} + \sum_{i \in I} A_{i,0} \) and \( v_2 \in A_{1,1} + \sum_{i \in I} A_{i,0} \), we have
\[
C := \left( A_{1,0} + \sum_{i \in I} A_{i,0} \right) \cap \left( A_{1,1} + \sum_{i \in I} A_{i,0} \right) = \langle \{v_2\} \cup \{v_i \mid i \in I\} \rangle.
\]

To compute further intersections we need to introduce some notation.

For \( i \in I \) let \( A_i \) be defined by
\[
A_i := A_{i,1} + \sum_{j \in I, j \neq i} A_{j,0}.
\]
Then
\[
A_i = \langle \{v_j \mid j \in I \setminus \{i\}\} \cup \{v_i + v_{i-1} + v_{i-3} + \cdots\} \rangle.
\]

For \( i, j \in I \) let \( A_{i,j} \) be defined by
\[
A_{i,j} := A_{i,1} + A_{j,1} + \sum_{\ell \in I, \ell \neq i,j} A_{\ell,0}.
\]
Then
\[
A_{i,j} = \langle \{v_\ell \mid \ell \in I \setminus \{i,j\}\} \cup \{v_i + v_{i-1} + v_{i-3} + \cdots, v_j + v_{j-1} + v_{j-3} + \cdots\} \rangle.
\]

To prove (8.5) we proceed with a number of steps.

**Step 1: \( k \) even and \( k > k_1 \).**

We prove that
\[
C \cap (A_{1,0} + A_k) = \langle \{v_2\} \cup \{v_j \mid j \in I \setminus \{k\}\} \rangle.
\]
Since we have
\[
A_{1,0} + A_k = A_{1,0} + \langle \{v_j \mid j \in I \setminus \{k\}\} \cup \{v_k + v_{k-1} + v_{k-3} + \cdots\} \rangle = \langle \{v_j \mid j \in I \setminus \{k\}\} \cup \{v_1, v_2, v_k + v_{k-1} + v_{k-3} + \cdots\} \rangle,
\]
it is obvious that
\[
\langle \{v_2\} \cup \{v_j \mid j \in I \setminus \{k\}\} \rangle \subseteq C \cap (A_{1,0} + A_k).
\]
Moreover, since \( \langle \{v_2\} \cup \{v_j \mid j \in I \setminus \{k\}\} \rangle \) has codimension 1 in \( C \), it suffices to show that \( v_k \notin A_{1,0} + A_k \). Suppose, by contradiction, that \( v_k \in A_{1,0} + A_k \). Then there exist \( \lambda_1, \lambda_2, \cdots \in \{0,1\} \) with
\[
v_k = \lambda_1 v_1 + \lambda_2 v_2 + \lambda_k (v_k + v_{k-1} + v_{k-3} + \cdots) + \sum_{j \in I \setminus \{k\}} \lambda_j v_j.
\]
But \( v_{k_1} \) occurs exactly once on the right hand side of this equation (note that \( k \) is even, \( k_1 \) is odd and \( k > k_1 \)), and we conclude \( \lambda_k = 0 \). But then
\[
v_k = \lambda_1 v_1 + \lambda_2 v_2 + \sum_{j \in I \setminus \{k\}} \lambda_j v_j,
\]
a contradiction. Hence, for all \( k > k_1 \) with \( k \) even, we have
\[
C \cap (A_{1,0} + A_k) = \langle \{v_2\} \cup \{v_j \mid j \in I \setminus \{k\}\} \rangle.
\]

Let \( I' := \{k \in I \mid k > k_1, k \text{ even}\} \). We conclude
\[
C' := C \cap (\cap_{k \in I'} (A_{1,0} + A_k)) = \cap_{k \in I'} (C \cap (A_{1,0} + A_k)) = \cap_{k \in I'} (\langle \{v_2\} \cup \{v_j \mid j \in I \setminus \{k\}\} \rangle) = \langle \{v_2\} \cup \{v_j \mid j \in I \setminus I'\} \rangle.
\]

Next, we prove that
\[
C'' := C' \cap (A_{1,1} + A_{k_1+1}) = \langle \{v_j \mid j \in I \setminus I'\} \rangle.
\]

We have
\[
A_{1,1} + A_{k_1+1} = A_{1,1} + \langle \{v_j \mid j \in I \setminus \{k_1 + 1\}\} \cup \{v_{k_1+1} + v_{k_1} + v_{k_1-2} + \cdots\} \rangle = \langle \{v_j \mid j \in I \setminus \{k_1 + 1\}\} \cup \{v_1 + v_3 + v_5 + \cdots, v_2 + v_4 + v_6 + \cdots, v_{k_1+1} + v_{k_1} + v_{k_1-2} + \cdots\} \rangle.
\]

Moreover, since \( \langle \{v_j \mid j \in I \setminus I'\} \rangle \) has codimension 1 in \( C' \), it suffices to show that \( v_2 \notin A_{1,1} + A_{k_1+1} \). Suppose, by contradiction, that \( v_2 \in A_{1,1} + A_{k_1+1} \). Then there exist \( \lambda_1, \lambda_2, \cdots \in \{0,1\} \) with
\[
v_2 = \lambda_1(v_1 + v_3 + v_5 + \cdots) + \lambda_2(v_2 + v_4 + v_6 + \cdots) + \sum_{j \in I \setminus \{k_1 + 1\}} \lambda_j v_j.
\]

But since \( v_{k_2} \) occurs exactly once on the right hand side of this equation, we conclude that \( \lambda_1 = 0 \); also, since \( v_{k_1} \) occurs only once on the right hand side of this equation, we conclude that \( \lambda_{k_1+1} = 0 \); further, since \( v_{k_1+1} \) occurs only once, we conclude that \( \lambda_2 = 0 \). But this is a contradiction.

**Step 2:** \( k \) even and \( k < k_1 \).

We prove that
\[
C'' \cap (A_{1,1} + A_{k,k_1+1}) = \langle \{v_j \mid j \in (I \setminus I') \setminus \{k\}\} \rangle.
\]

We have
\[
A_{1,1} + A_{k,k_1+1} = A_{1,1} + \langle \{v_j \mid j \in I \setminus \{k, k_1 + 1\}\} \cup \{v_1 + v_{k-1} + v_{k-3} + \cdots, v_{k_1+1} + v_{k_1} + v_{k_1-2} + \cdots\} \rangle = \langle \{v_j \mid j \in I \setminus \{k, k_1 + 1\}\} \cup \{v_1 + v_3 + v_5 + \cdots, v_2 + v_4 + v_6 + \cdots, v_k + v_{k_1} + v_{k_3} + \cdots, v_{k_1+1} + v_{k_1} + v_{k_1-2} + \cdots\} \rangle.
\]

It is clear that
\[
\langle \{v_j \mid j \in (I \setminus I') \setminus \{k\}\} \rangle \subseteq C'' \cap (A_{1,1} + A_{k,k_1+1}).
\]

Moreover, since \( \langle \{v_j \mid j \in (I \setminus I') \setminus \{k\}\} \rangle \) has codimension 1 in \( C'' \), it suffices to show that \( v_k \notin A_{1,1} + A_{k,k_1+1} \). Suppose, by contradiction, that \( v_k \in A_{1,1} + A_{k,k_1+1} \). Then there exist \( \lambda_1, \lambda_2, \cdots \in \{0,1\} \) with
\[
v_k = \lambda_1(v_1 + v_3 + v_5 + \cdots) + \lambda_2(v_2 + v_4 + v_6 + \cdots) + \sum_{j \in I \setminus \{k,k_1+1\}} \lambda_j v_j.
\]
This implies that on the right hand side of this equation the coefficient of $v_k$ is equal to 1 and all other coefficients of $v_j$, $j \neq k$, are equal to 0. Following is the set of respective coefficients of $\{v_{k+1}, v_k, v_1, v_2\}$:

\[
\{\lambda_2 + \lambda_{k+1} = 0, \lambda_1 + \lambda_{k+1} = 0, \lambda_1 + \lambda_k + \lambda_{k+1} = 0, \lambda_2 = 0\}.
\]

It follows that $\lambda_2 = \lambda_1 = \lambda_k = \lambda_{k+1} = 0$. So $\lambda_2 + \lambda_k = 0$, but this is a contradiction because $\lambda_2 + \lambda_k$ is the coefficient of $v_k$ and should be equal to 1.

Hence, for all $k < k_1$ with $k$ even, we have

\[
C'' \cap (A_{1,1} + A_{k,k+1}) = \langle \{v_2\} \cup \{v_j \mid j \in (I \setminus I') \setminus \{k\}\} \rangle.
\]

Let $I'' := \{k \in I \mid k < k_1, k \text{ even}\}$.

We conclude

\[
D := C'' \cap (\cap_{k \in I''} (A_{1,1} + A_{k,k+1})) = \cap_{k \in I''} (C'' \cap (A_{1,1} + A_{k,k+1})) = \cap_{k \in I'} (\langle \{v_j \mid j \in (I \setminus I') \setminus \{k\}\} \rangle) = \langle \{v_j \mid j \in I \setminus (I' \cup I'')\} \rangle = \langle \{v_j \mid j \in I, j \text{ odd}\} \rangle.
\]

**Step 3:** $k$ odd and $k < k_1$.

Let denote $I = I_o \cup I_e$, where $I_o$ respectively $I_e$ are subsets of odd respectively even numbers in $I$. We prove that

\[
D \cap (A_{1,1} + A_{k,k+1}) = \langle \{v_j \mid j \in I_o \setminus \{k\}\} \rangle.
\]

We have

\[
A_{1,1} + A_{k,k+1} = A_{1,1} + \langle \{v_j \mid j \in I \setminus \{k, k+1\}\} \cup \{v_k + v_{k-1} + v_{k-3} + \cdots, v_{k+1} + v_k + v_{k-2} + \cdots\} \rangle = \langle \{v_j \mid j \in I \setminus \{k, k+1\}\} \cup \{v_1 + v_3 + v_5 + \cdots, v_2 + v_4 + v_6 + \cdots, v_k + v_{k-1} + v_{k-3} + \cdots, v_{k+1} + v_k + v_{k-2} + \cdots\} \rangle.
\]

Observe that

\[
\langle \{v_j \mid j \in I_o \setminus \{k\}\} \rangle \subseteq D \cap (A_{1,1} + A_{k,k+1}).
\]

Moreover, since $\langle \{v_j \mid j \in I_o \setminus \{k\}\} \rangle$ has codimension 1 in $D$, it suffices to show that $v_k \notin A_{1,1} + A_{k,k+1}$. Suppose, by contradiction, that $v_k \in A_{1,1} + A_{k,k+1}$. Then there exist $\lambda_1, \lambda_2, \cdots \in \{0, 1\}$ with

\[
v_k = \lambda_1(v_1 + v_3 + v_5 + \cdots) + \lambda_2(v_2 + v_4 + v_6 + \cdots) + \lambda_k(v_k + v_{k-1} + v_{k-3} + \cdots) + \lambda_{k+1}(v_{k+1} + v_k + v_{k-2} + \cdots) + \sum_{j \in I \setminus \{k,k+1\}} \lambda_j v_j.
\]

This says that on the right hand side of this equation the coefficient of $v_k$ is equal to 1 and all other coefficients of $v_j$, $j \neq k$, are equal to 0. Following is the set of respective coefficients of $\{v_{k+1}, v_k, v_1, v_2, v_k\}$:

\[
\{\lambda_2 + \lambda_{k+1} = 0, \lambda_1 + \lambda_{k+1} = 0, \lambda_2 + \lambda_k = 0, \lambda_1 = 0\}.
\]

It follows that $\lambda_1 = \lambda_{k+1} = \lambda_2 = \lambda_k = 0$. So $\lambda_1 + \lambda_k + \lambda_{k+1} = 0$, but this is a contradiction because $\lambda_1 + \lambda_k + \lambda_{k+1}$ is the coefficient of $v_k$ and should be equal to 1.

Hence, for all $k < k_1$ with $k$ odd, we have

\[
D \cap (A_{1,1} + A_{k,k+1}) = \langle \{v_j \mid j \in I_o \setminus \{k\}\} \rangle.
\]

23
Lemma 6 Suppose that \( k_1 + k_2 \equiv 1 \mod 2 \). Then equation (8.5) is satisfied.

The proof of Lemma 5 is similar to that of Lemma 4, which we omit.

The next lemma deals with the last subcase.

Lemma 6 Suppose that \( k_1 + k_2 \equiv 1 \mod 2 \). Then equation (8.5) is satisfied.
Proof. W.l.o.g. we assume \( k_1 \equiv 1 \) mod 2 and \( k_2 \equiv 0 \) mod 2.

We give a brief description of the steps that need to be carried out to prove (8.5) without showing the detail.

Step 1: Prove that
\[
C := (A_{1,0} + \sum_{i \in I} A_{i,0}) \cap (A_{1,1} + \sum_{i \in I} A_{i,0}) = \langle \{v_j \mid j \in I\} \rangle.
\]

Step 2: \( k \) odd and \( k < k_2 \).
- Prove
  \[
  C \cap (A_{1,1} + A_k) = \langle \{v_j \mid j \in I \setminus \{k\}\} \rangle
  \]
  by showing \( v_k \not\in (A_{1,1} + A_k) \).
- Let \( I' := \{k \in I \mid k < k_2, \ k \ \text{odd}\} \). Then we have
  \[
  C' := C \cap (\cap_{k \in I'} (A_{1,0} + A_k)) = \cap_{k \in I'} (C \cap (A_{1,0} + A_k)) =
  \cap_{k \in I'} (\langle \{v_j \mid j \in I \setminus \{k\}\} \rangle) = \langle \{v_j \mid j \in I \setminus I'\} \rangle.
  \]

Step 3: \( k \) odd and \( k > k_2 \).
- Prove
  \[
  C \cap (A_{1,0} + A_k) = \langle \{v_j \mid j \in I \setminus \{k\}\} \rangle
  \]
  by showing \( v_k \not\in (A_{1,0} + A_k) \).
- Let \( I'' := \{k \in I \mid k > k_2, \ k \ \text{odd}\} \). Then we have
  \[
  C'' := C' \cap (\cap_{k \in I''} (A_{1,0} + A_k)) = \cap_{k \in I''} (C' \cap (A_{1,0} + A_k)) =
  \cap_{k \in I''} (\langle \{v_j \mid j \in I \setminus \{I' \cup k\}\} \rangle) = \langle \{v_j \mid j \in I \setminus (I' \cup I'')\} \rangle = \langle \{v_j \mid j \in I_e\} \rangle,
  \]
  where \( I_e \) is the subset of all even numbers in \( I \).

Step 4: \( k \) even and \( k < k_1 \).
- Prove
  \[
  C'' \cap (A_{1,1} + A_k) = \langle \{v_j \mid j \in I_e \setminus \{k\}\} \rangle
  \]
  by showing \( v_k \not\in (A_{1,1} + A_k) \).
- Let \( J := \{k \in I_e \mid k < k_1, \ k \ \text{even}\} \). Then we have
  \[
  D := C'' \cap (\cap_{k \in J} (A_{1,1} + A_k)) = \cap_{k \in J} (C'' \cap (A_{1,1} + A_k)) =
  \cap_{k \in J} (\langle \{v_j \mid j \in I_e \setminus \{k\}\} \rangle) = \langle \{v_j \mid j \in I \setminus J\} \rangle.
  \]

Step 5: \( k \) even and \( k > k_1 \).
- Prove
  \[
  D \cap (A_{1,0} + A_k) = \langle \{v_j \mid j \in I_e \setminus \{J \cup k\}\} \rangle
  \]
  by showing \( v_k \not\in (A_{1,0} + A_k) \).
Let \( J' := \{ k \in I_e \mid k > k_1, k \text{ even} \} \). Then we have
\[
D' := D \cap (\cap_{k \in J'} (A_{1,0} + A_k)) = \cap_{k \in J'} (D \cap (A_{1,0} + A_k)) =
\cap_{k \in J'} (\langle \{ v_j \mid j \in I_e \setminus (J \cup k) \} \rangle) = \langle \{ v_j \mid j \in I \setminus (J \cup J') \} = \{0\} \rangle,
\]
which proves (8.5). \( \square \)

9 Some open questions

As we have seen from Theorem 1 that the logarithmic signature \( \beta \) constructed from the Baumeister-de Wiljes method is tame provided the logarithmic signatures \([A_{1,j_1}, \ldots, A_{s,j_s}]\) and \( \theta \) are known and tame. Obviously, if \( \theta \) or/and \([A_{1,j_1}, \ldots, A_{s,j_s}]\) are not tame, even if they are known, no efficient method is known regarding the factorization with respect to \( \beta \). It is worth finding an answer to the following interesting problem.

**Question 1** Suppose \([A_{1,j_1}, \ldots, A_{s,j_s}], 1 \leq j_i \leq r_i, \) and \( \theta \) are tame but they are not known. Suppose further that \( \beta \) is strongly aperiodic. Can elements of \( \mathcal{G} \) be (efficiently) factorized with respect to \( \beta \)?

The result of the cryptanalysis of the enhanced version of MST\(_3\) [12] has shown that the scheme is secure when fused transversal logarithmic signatures are used. More precisely, fused transversal logarithmic signatures withstand the powerful Matrix-Permutation attack, a type of chosen plaintext attack, against the scheme and moreover one can determine a bound on the complexity of the attack for a given fused transversal logarithmic signature. It turns out that the complexity is less than the input length of the scheme, see [12]. By virtue of the Baumeister-de Wiljes construction method we would conjecture that the complexity of the Matrix-Permutation attack against \( MST_3 \) is of size of the input length, when strongly aperiodic logarithmic signatures constructed in this paper are used. Hence we put the following challenging and important question.

**Question 2** Determine the complexity of the Matrix-Permutation attack of the enhanced version of \( MST_3 \), when strongly aperiodic logarithmic signatures constructed in this paper are used.

Recall that fusing blocks of a strongly aperiodic logarithmic signature constructed in this paper remains a logarithmic signature of Baumeister-de Wiljes type. Furthermore, a logarithmic signature \( \beta = [B_1, \ldots, B_s] \) used in \( MST_3 \) of Question 2 should have a reasonable block size, say, \( |B_i| \geq 2^6 \) for \( 1 \leq i \leq s \). So, \( \beta \) is obtained by fusing blocks of a logarithmic signature constructed in Sections 7 and 8.

10 Conclusion

We introduced the concept of strongly aperiodic logarithmic signatures, having properties suitable for use in cryptosystem \( MST_3 \). We developed an algebraic approach based on the Baumeister-de Wiljes method which enables the construction of such logarithmic signatures for elementary abelian \( p \)-groups. The existence of strongly aperiodic logarithmic signatures not only extends the private
key space of $MST_3$ but would significantly contribute to its security. It is therefore worthwhile to investigate further method for constructing strongly aperiodic logarithmic signatures for abelian groups.
