KOSZUL ALGEBRAS AND THE QUANTUM MACMAHON MASTER THEOREM

PHUNG HÔ HAI AND MARTIN LORENZ

ABSTRACT. We give a new proof of the quantum version of MacMahon’s Master Theorem due to Garoufalidis, Le and Zeilberger by deriving it from known facts about Koszul algebras.

1. INTRODUCTION

In [3], Garoufalidis, Le and Zeilberger prove a quantum version of MacMahon’s celebrated “Master Theorem” [6, pp. 97–98]. As stated in [3], the generalization was motivated in part by considerations in quantum topology and knot theory, and it also answers a long-standing open question by G. Andrews [1, Problem 5]. An abundance of different proofs of the original Master Theorem can be found in the literature; the quantum-generalization in [3] is proved by an adaptation of the “operator-elimination” proof given in [10]. Our goal here is to derive the quantum MacMahon Master Theorem of Garoufalidis, Le, and Zeilberger from basic properties of Koszul algebras which fairly effortlessly lead to a generalized MacMahon identity. This identity is stated as equation (8) below; the quantum MacMahon Master Theorem is the special case of (8) where the Koszul algebra in question is the so-called quantum affine n-space. Thus, neither the main result of this note nor the methods employed are ours but we believe that the connection between Koszul algebras and the quantum Master Theorem deserves to be explicitly stated and fully exploited. This connection was in fact already briefly mentioned in the last section of [3], but the proof given here appears to be new.

We have tried to keep this note reasonably self-contained and accessible to readers unfamiliar with Koszul algebras. Sections 2 and 3 serve to deploy the pertinent background material concerning Koszul algebras and cocharacters, respectively, in some detail. The operative technicalities for our proof are collected in Lemmas 1 and 2 below; they are presented here with full proofs for lack of a suitable reference. The quantum MacMahon Master Theorem [3, Theorem 1] is then stated and proved in Section 4. The short final Section 5 discusses certain modifications of the MacMahon identity.

Our basic reference for Koszul algebras are Manin’s notes [7]; for bialgebras, our terminology follows Kassel [5]. We work over a commutative base field k except in 3.1 and 3.2 where k can be any commutative ring at no extra cost. Throughout, ⊗ will stand for ⊗k.

2. KOSZUL ALGEBRAS

2.1. Quadratic algebras. A quadratic algebra is a factor of the tensor algebra T(V) of some finite-dimensional k-vector space V modulo the ideal generated by some subspace R(A) ⊆ T(V)2 = V ⊗2. Thus, A ∼= T(V)/R(A). The natural grading of T(V) descends to a grading A = ⊕d≥0 A_d of A with A_0 = k and A_1 ∼= V. In practice, one often fixes a k-basis x_1, ..., x_n of V. Then T(V) can be viewed as the free algebra k⟨x_1, ..., x_n⟩ and the images x_i = x_i mod R(A) of the elements x_i in A form a set of generators for A.

Key words and phrases. MacMahon’s Master Theorem, Koszul algebra, quantum matrix, quantum determinant, coalgebra, cocharacter.

PHH is supported by the DFG with a Heisenberg-Fellowship.

ML’s research is supported in part by a grant from the NSA.
Example (Quantum affine $n$-space). This is the quadratic algebra $A = A_q^{n|0}$ that is defined, for a fixed $0 \neq q \in \mathbb{k}$, as the factor of $\mathbb{k}\langle \tilde{x}_1, \ldots, \tilde{x}_n \rangle$ modulo the ideal generated by the 2-homogeneous elements $\tilde{x}_j \tilde{x}_i - q \tilde{x}_i \tilde{x}_j$ for $1 \leq i < j \leq n$. Thus, the algebra $A_q^{n|0}$ is generated by elements $x_1, \ldots, x_n$ satisfying the relations
\begin{equation}
 x_j x_i = q x_i x_j \text{ for } i < j.
\end{equation}

2.2. Quadratic dual. Given a quadratic algebra $A \cong T(V)/(R(A))$, consider the subspace $R(A)^\perp$ of the linear dual $(V^\otimes 2)^*$ consisting of all linear form on $V^\otimes 2$ that vanish on $R(A)$. Identifying $(V^\otimes 2)^*$ with $V^* \otimes 2$ in the usual way, we may view $R(A)^\perp \subseteq V^* \otimes 2$ and hence define a new quadratic algebra by
\begin{equation}
 A^! = T(V^*)/(R(A)^\perp).
\end{equation}

The algebra $A^!$ is called the quadratic dual of $A$. If $\tilde{x}_1, \ldots, \tilde{x}_n$ is a fixed $\mathbb{k}$-basis of $V$, as above, then one usually chooses the dual basis $\tilde{x}^1, \ldots, \tilde{x}^n$ for $V^*$: $\langle \tilde{x}^i, \tilde{x}_j \rangle = \delta_{i,j}$, where $\langle \ldots \rangle$ denotes evaluation. This yields algebra generators $x^i = \tilde{x}^i \mod R(A)^\perp$ for $A^!$.

Example (Quantum exterior algebra). Consider the algebra $A = A_q^{0|n}$ as above. The quadratic dual $A^!$ is denoted $A_q^{0|n}$ in [7]. The above procedure yields algebra generators $x^1, \ldots, x^n$ for $A_q^{0|n}$ satisfying the defining relations $x^i x^j = 0$ for all $\ell$ and $x^i x^j + q x^j x^i = 0$ for $i < j$.

2.3. The bialgebra end $A$. Given quadratic algebras $A \cong T(A)/R(A))$ and $B \cong T(B)/R(B))$, one defines the quadratic algebra $A \bullet B = T(A \otimes B)/R(A \otimes B))$. Here, $S_{23}: A^\otimes 2 \otimes B^\otimes 2 \rightarrow (A \otimes B \otimes B)^\otimes 2$ switches the second and third factors.

The algebra $\text{end } A = A^! \bullet A$ is particularly important. Identifying $A_1$ with $V$ as above, we have
\begin{equation}
 \text{end } A = T(V^* \otimes V)/((S_{23}(R(A)^\perp \otimes R(A)))).
\end{equation}

Fix generators $x_i = \tilde{x}_i \mod R(A)$ for $A$ and $x^i = \tilde{x}^i \mod R(A)^\perp$ for $A^!$ as in 2.1 and 2.2. Then the elements $\tilde{z}_i^\ell = \tilde{x}^i \otimes \tilde{x}_j$ form a basis of $V^* \otimes V^*$ and their images $z_i^\ell = \tilde{z}_i^\ell \mod R(\text{end } A)$ form algebra generators for $\text{end } A$. The algebra $\text{end } A$ is endowed with a comultiplication
\begin{equation}
 \Delta: \text{end } A \rightarrow \text{end } A \otimes \text{end } A, \quad \Delta(z_i^\ell) = \sum_{\ell} z_i^\ell \otimes z_i^\ell
\end{equation}

and a counit
\begin{equation}
 \epsilon: \text{end } A \rightarrow \mathbb{k}, \quad \epsilon(z_i^\ell) = \delta_{i,j} \text{ (Kronecker delta)}
\end{equation}

which make it a bialgebra over $\mathbb{k}$; see [7, 5.7 and 5.8]. Furthermore, defining a coaction
\begin{equation}
 \delta_A: A \rightarrow \text{end } A \otimes A, \quad \delta_A(x_i) = \sum_{j} z_i^\ell \otimes x_j,
\end{equation}

the algebra $A$ becomes a left $\text{end } A$-comodule algebra: $\delta_A$ is a $\mathbb{k}$-algebra map that makes $A$ a comodule for $\text{end } A$; see [7, 5.4].

Example (Right quantum matrices). Returning to the case $A = A_q^{n|0}$, we describe the algebra $\text{end } A_q^{n|0}$. Using the notation and the relations of the Examples in 2.1 and 2.2, the foregoing leads to the following relations for $R(\text{end } A_q^{n|0}) \subseteq (V^* \otimes V)^\otimes 2$: for all $\ell$ and $i < j$ we have a generator $z_i^\ell \otimes z_j^\ell - q z_j^\ell \otimes z_i^\ell$, and for all $i < j$ and $k < \ell$ there is $z_j^k \otimes z_i^\ell - q z_i^\ell \otimes z_j^k + q z_i^\ell \otimes z_k^\ell - q^2 z_i^\ell \otimes z_k^k$. After multiplying the second set of generators with $q^{-1}$, we obtain the following relations between the generators $z_i^\ell$ of $\text{end } A_q^{n|0}$:
\begin{align}
 (4) & \quad z_i^\ell z_j^\ell = q z_j^\ell z_i^\ell \quad \text{for all } \ell \text{ and } i < j \quad \text{(column commutation relations)} \\
 (5) & \quad z_j^k z_i^\ell z_i^\ell = q^{-1} z_j^k z_i^\ell z_i^\ell - q z_i^\ell z_j^k \quad \text{for } i < j \text{ and } k < \ell \quad \text{(cross commutation relations)}
\end{align}

Thus, using the terminology of [3], the $n \times n$-matrix $Z = (z_i^\ell)$ is a right-quantum matrix.
2.4. The Koszul complex. For any quadratic algebra $A$, one can define Koszul complexes

$$K^e_i(A) : \ 0 \to A^*_i \to A^*_{i-1} \otimes A_1 \to \cdots \to A^*_1 \otimes A_{\ell-1} \to A_\ell \to 0$$

as in [7, 9.6]. The quadratic algebra $A$ is called a Koszul algebra if all complexes $K^e_i(A)$ for $\ell > 0$ are exact. It is known that if $A$ and $B$ are Koszul then so are $A^1$ and $A \bullet B$. Moreover, if $A$ has a so-called PBW-basis consisting of certain standard monomials, then $A$ is Koszul; see, e.g., [8, Theorem 4.3.1]. This applies in particular to the algebras $A = A_q^{[0]}$ [8, 4.2 Example 1].

Lemma 1. Let $A$ be a quadratic algebra. Then all $A_i$ and all $A^*_i$ are (left) comodules over end $A$, and hence so are the components $K^e_i(A) = A^*_i \otimes A_i$ of the Koszul complex. Moreover, the Koszul differential is an end $A$-comodule map.

Proof. We will write $B = \text{end} A$ for brevity; so $B_1 = V^* \otimes V$. Equation (3) shows that $\delta A$ sends $V = A_1$ to $B_1 \otimes V$. Thus, $A_1$ is mapped to $B_i \otimes A_i \subseteq B \otimes A_i$, and so each $A_i$ is a $B$-comodule. Moreover, as is shown in [7, 5.5], the map $\delta A$ comes from a map $\delta : T(V) \to T(B_1) \otimes T(V)$, $\delta(x_i) = z_i^{ij} \otimes x_j$, which satisfies $\delta(R(A)) \subseteq R(B) \otimes T(V) + T(B_1) \otimes R(A)$. Following $\delta$ by the canonical map $T(B_1) \to B = T(B_1)/R(B)$ tensored with $\text{Id}_{T(V)}$, we obtain a map

$$\delta' : T(V) \to B \otimes T(V), \quad \delta'(x_i) = \sum_j z_i^{ij} \otimes x_j$$

satisfying $\delta' (V^{\otimes i}) \subseteq B_i \otimes V^{\otimes i}$ and $\delta' (R(A)) \subseteq B \otimes R(A)$. Therefore, all $V^{\otimes \bullet}$ are $B$-comodules and $R(A)$ a $B$-subcomodule of $V^{\otimes 2}$. More generally, the subspaces $V^{\otimes i} \otimes R(A) \otimes V^{\otimes m-2-i}$ for $0 \leq i \leq m-2$ are $B$-subcomodules of $V^{\otimes m}$, and hence so are the subspaces $\bigcap_{i=0}^{m-2} V^{\otimes i} \otimes R(A) \otimes V^{\otimes m-2-i}$ and $R_m(A) := \bigcap_{i=0}^{m-2} V^{\otimes i} \otimes R(A) \otimes V^{\otimes m-2-i}$. Following [7, 9.6], we identify the former with the linear dual of $A_m^\dagger = V^* \otimes R(A) \otimes V^{\otimes m-2-i}$; so

$$A_m^\dagger = \bigcap_{i=0}^{m-2} V^{\otimes i} \otimes R(A) \otimes V^{\otimes m-2-i}.$$ (7)

Also according to [ibid, 9.6], the diagram

$$A_{m+1}^\dagger \otimes V^{\otimes n-1} \quad \leftrightarrow \quad A_m^\dagger \otimes V^{\otimes n}$$

$$A_{m+1}^\dagger \otimes R_{n-1}(A) \quad \leftrightarrow \quad A_m^\dagger \otimes R_n(A)$$

induces the Koszul differential

$$A_{m+1}^\dagger \otimes A_{n-1} = A_m^\dagger \otimes \frac{V^{\otimes n-1}}{R_{n-1}(A)} \to A_m^\dagger \otimes \frac{V^{\otimes n}}{R_n(A)} = A_m^\dagger \otimes A_n$$

Since all spaces here are $B$-comodules, the differential is a $B$-comodule map. \hfill \Box

3. Bialgebras and Cocharacters

3.1. The Grothendieck ring. For now, let $B$ denote an arbitrary bialgebra over some commutative base ring $k$. We let $R_B$ denote the Grothendieck ring of all (left) $B$-comodules that are finitely generated (f.g.) projective over $k$. Thus, for each such $B$-comodule, $V$, there is an element $[V] \in R_B$ and any short exact sequence $0 \to U \to V \to W \to 0$ of $B$-comodules (f.g. projective over $k$) gives rise to an equation $[V] = [U] + [W]$ in $R_B$. Multiplication in $R_B$ is given by the tensor product of $B$-comodules; see [5, III.6].
3.2. Cocharacters. Continuing with the notation of 3.1, let \( V \) be a \( B \)-comodule that is f.g. projective over \( k \). The structure map \( \delta_V : V \to B \otimes V \) is an element of \( \text{Hom}_k(V, B \otimes V) \). Using the standard isomorphisms \( \text{Hom}_k(V, B \otimes V) \cong B \otimes V \otimes V^* \) (see, e.g., \([2, \text{II.4.2}]\)) and letting \( \langle \, , \, \rangle : V \otimes V^* \to k \) denote the evaluation map, we have a homomorphism

\[ \text{Hom}_k(V, B \otimes V) \cong B \otimes V \otimes V^* \xrightarrow{\text{Id}_B \otimes (\, , \, )} B \otimes k \cong B . \]

The image of \( \delta_V \) under this map will be denoted by \( \chi_V \). If \( V \) is free over \( k \), with basis \( \{ v_i \} \), and \( \delta_V(v_j) = \sum_i b_{i,j} \otimes v_i \) then

\[ \chi_V = \sum_i b_{i,i} . \]

Lemma 2. The map \( [V] \mapsto \chi_V \) yields a well-defined ring homomorphism \( \chi : R_B \to B \).

Proof. The assertion is equivalent to the identities \( \chi_{V \otimes W} = \chi_V \chi_W \) for any two \( B \)-comodule \( V \) and \( W \) (f.g. projective over \( k \)) and \( \chi_V = \chi_U + \chi_W \) for any short exact sequence \( 0 \to U \xrightarrow{\mu} V \xrightarrow{\pi} W \to 0 \). Both are easy to check; we sketch the proof of the second identity. Fix \( k \)-linear splittings \( \sigma : W \to V \) and \( \tau : V \to U \) with \( \tau \circ \mu = \text{Id}_U \), \( \sigma \circ \sigma = \text{Id}_W \) and \( \sigma \circ \pi + \mu \circ \tau = \text{Id}_V \). Under the canonical isomorphism \( V \otimes V^* \cong \text{End}_k(V) \), evaluation \( (\, , \, ) \) becomes the trace map \( \text{trace}_V : \text{End}_k(V) \to k \). For any \( \varphi \in \text{End}_k(V) \), we have \( \text{trace}_V(\varphi) = \text{trace}_V(\sigma \circ \varphi \circ \mu) + \text{trace}_V(\pi \circ \varphi \circ \sigma) \). The equation \( \mu = (\text{Id}_B \otimes \mu) \circ \delta_U \) gives \( \mu = (\text{Id}_B \otimes \tau) \circ \delta_V \circ \mu \). Similarly, \( \mu = (\text{Id}_B \otimes \pi) \circ \delta_V \circ \sigma \). Therefore, \( \chi_V = (\text{Id}_B \otimes \text{trace}_V)(\delta_V) = (\text{Id}_B \otimes \text{trace}_V)(\delta_U) + (\text{Id}_B \otimes \text{trace}_W)(\delta_W) = \chi_U + \chi_W \), as desired. \( \square \)

3.3. Application to Koszul algebras. Returning to the case of a Koszul algebra \( A \) over a field \( k \), we apply the foregoing to the bialgebra \( B = \text{end}_A \). By Lemma 1, the (exact) Koszul complex \( K^\bullet(A) \) for \( \ell > 0 \) gives an equation in \( R_B \):

\[ \sum_i (-1)^i [A_i^\ast][A_{i-i}] = 0 . \]

Equivalently, defining the Poincaré series \( P_A(t) = \sum_i [A_i]t^i \) and \( P_{A^\ast}(t) = \sum_i [A_i^\ast]t^i \), we have

\[ P_A(t)P_{A^\ast}(-t) = 1 \]

in the power series ring \( R_B[t] \). Applying the ring homomorphism \( \chi[t] : R_B[t] \to B[t] \) (Lemma 2), this equation becomes the following equation in \( B[t] \):

\[ \left( \sum_{\ell \geq 0} \chi_A t^\ell \right) \left( \sum_{m \geq 0} (-1)^m \chi_{A^\ast} t^m \right) = 1 . \]

Since the coactions \( \delta_A \) and \( \delta_A^\ast \) in (3) and (6) respect the grading, both factors actually belong to the subring \( \prod_{n \geq 0} B_n t^n \) of \( B[t] \).

4. PROOF OF THE QUANTUM MACMAHON MASTER THEOREM

The quantum MacMahon Master Theorem \([3, \text{Theorem 1}]\) is the case \( A = A_q^{n0} \) of equation (8). In detail, choose generators \( x_1, \ldots, x_n \) for \( A \) as in 2.1. For each \( n \)-tuple \( m = (m_1, \ldots, m_n) \in \mathbb{Z}_{\geq 0}^n \), put \( x_m := x_1^{m_1}x_2^{m_2} \cdots x_n^{m_n} \in A \). Then the homogeneous component \( A_\ell \) has a \( k \)-basis consisting of elements \( x_m \) with \( |m| = m_1 + m_2 + \cdots + m_n = \ell \). (This is the PBW-basis of \( A_q^{n0} \) referred to earlier.) With respect to this basis, the coaction \( \delta_A \) of \( B = \text{end}_A \) on \( A_\ell \) in (3) has the form

\[ \delta_A(x_m) = \delta_A(x_1)^{m_1}\delta_A(x_2)^{m_2} \cdots \delta_A(x_n)^{m_n} = \sum_{r \in \mathbb{Z}_{\geq 0}} b_{r,m} \otimes x_r \]
for uniquely determined $b_{r,m} \in B_\ell$. In particular, $G(m) := b_{m,m} \in B_{|m|}$ has the same meaning as in [3]. Taking the trace we obtain the equality

$$ \chi_{A_\ell} = \sum_{m : |m| = \ell} G(m). $$

In order to deal with the second factor in equation (8), we identify $A_{1,m}^*$ with a subspace of $T(V)_m = V_\otimes m$ as in (7), and $T(V)$ with the free algebra $k\langle \tilde{x}_1, \ldots, \tilde{x}_n \rangle$ as in 2.1. Then $A_{1,m}^*$ has a basis consisting of the elements

$$ \land J := \sum_{\pi \in S_m} (-q)^{-l(\pi)} \tilde{x}_{j_1} \otimes \tilde{x}_{j_2} \otimes \ldots \otimes \tilde{x}_{j_m}, $$

where $J = (j_1 < j_2 < \ldots < j_m)$ is an $m$-element subset of $\{1, \ldots, n\}$, $S_m$ is the symmetric group and $l(\pi)$ denotes the number of pairs $(i, j)$ with $1 \leq i < j \leq m$ and $\pi i > \pi j$. Indeed, recalling the fact that $R(A_1^*) = R(A)^\perp$ is generated by the elements $\tilde{x}_j^\ell \tilde{x}_i^\ell$ for all $\ell$ and $q\tilde{x}_j^\ell + q\tilde{x}_i^\ell = 0$ for $i < j$ (see 2.2), it is straightforward to check that $\land J$ vanishes on $R_m(A)$. Hence, $\land J$ belongs to $A_{1,m}^*$. Furthermore, the elements $\land J$ are obviously linear independent over $k$ and their number is $\binom{n}{m}$ which is equal to the dimension of $A_m$. We claim that the coaction $\delta'$ of $B = \text{end } A$ on $A_{1,m}^*$ in equation (6) has the form

$$ \delta'(\land J) = \det_q(Z_J) \otimes \land J + \text{other terms}, $$

where

$$ \det_q(Z_J) = \sum_{\pi \in S_m} (-q)^{-l(\pi)} z_{j_1}^{j_1} z_{j_2}^{j_2} \ldots z_{j_m}^{j_m} $$

denotes the quantum determinant (as defined in [9]) of the submatrix $Z_J = (z_{i,j}^q)_{i,j \in J}$ of the generic $n \times n$ right-quantum matrix $Z = (z_{i,j}^q)$ as in 2.3. In order to prove (10), it suffices to show that, for $J = (1, 2, \ldots, n) = [1, n]$, we have

$$ \delta'(\land [1, n]) = \det_q(Z) \otimes \land [1, n]. $$

To this end, note that the element $\land [1, n]$ spans the one-dimensional $B$-submodule $A_{1,n}^*$ of $V_\otimes n$. Hence, $\delta'(\land [1, n]) = D \otimes \land [1, n]$ for some group-like element $D \in B$; cf. [7, 8.2]. We need to show that $D = \det_q(Z) = \sum_{\pi \in S_n} (-q)^{-l(\pi)} z_{\pi 1}^{\pi 1} z_{\pi 2}^{\pi 2} \ldots z_{\pi n}^{\pi n}$. But equation (6) readily implies that

$$ \delta'(\tilde{x}_1 \otimes \ldots \otimes \tilde{x}_n) = z_{\pi 1}^{\pi 1} \ldots z_{\pi n}^{\pi n} \otimes \tilde{x}_1 \otimes \ldots \otimes \tilde{x}_n + \text{other terms}. $$

Multiplying with $(-q)^{-l(\pi)}$ and summing up on $\pi$ we see that $\delta'(\land [1, n]) = \det_q(Z) \otimes \tilde{x}_1 \otimes \ldots \otimes \tilde{x}_n + \text{other terms}$. This implies (12), thereby completing the proof of (10). Therefore, the cocharacter of $A_{1,m}^*$ is given by

$$ \chi_{A_{1,m}^*} = \sum_{J \subseteq \{1, \ldots, n\}} |J| = m \det_q(Z_J). $$

To summarize, we rephrase equation (8) with (9) and (13) using the notation of [3]:

**Theorem 3** (Garoufalidis, Le and Zeilberger). Let $A$ denote the $k$-algebra generated by $x_1, \ldots, x_n$ subject to the relations (1), $B$ the $k$-algebra generated by $z_1, \ldots, z_n$ subject to (4) and (5), and let $Z = (z_{i,j}^q)$ denote the generic right-quantum $n \times n$-matrix. Consider the elements $X_i = \sum_{j \in I} z_{i,j}^q x_j \in B \otimes A = \bigoplus_m B \otimes x^m$, where $m$ runs over the $n$-tuples $m = (m_1, \ldots, m_n) \in \mathbb{Z}_{\geq 0}^n$ and $x^m := x_1^{m_1} x_2^{m_2} \ldots x_n^{m_n}$. Define power series in $B[1]$ by

$$ \text{Bos}(Z) := \sum_{\ell \geq 0} \sum_{m : |m| = \ell} G(m) t^\ell, $$

where $G(m)$ is the same meaning as in [3].
where $G(m)$ is the $B$-coefficient of $x^m$ in $X^m = X_1^{m_1} X_2^{m_2} \ldots X_n^{m_n}$, and
\[
\text{Ferm}(Z) := \sum_{m \geq 0} \sum_{J \subseteq \{1, \ldots, n\} \atop |J| = m} (-1)^m \det_q(Z_J) t^m
\]
with $\det_q(Z_J)$ as in (11). Then:
\[
\text{Bos}(Z) \cdot \text{Ferm}(Z) = 1.
\]

5. **Modifying the MacMahon identity**

Applying endomorphisms of $B[t]$ to the generalized MacMahon identity (8), we obtain new versions of this identity. In this section, we discuss a particular example for the case $A = A_q^{n/0}$. As usual, we let $B = \text{end}_A A$.

The algebraic torus $T = (k^*)^n$ acts on $B$ via
\[
\tau(z_i^j) = c_j z_i^j
\]
for $\tau = (c_1, \ldots, c_n) \in T$. Indeed, $\tau$ respects the relations (4) and (5) of $B$, and hence $\tau$ defines a graded algebra automorphism of $B$. Note however that, unless $\tau = 1$, the automorphism $\tau$ does not preserve the comultiplication $\Delta$ of $B$ in (2) but rather is a homomorphism of left $B$-comodules, that is, $\Delta \circ \tau = (\text{Id}_B \otimes \tau) \circ \Delta$. Applying $\tau = (c_1, \ldots, c_n)$ to the cocharacters of $A_\tau$ and $A_{\tau^*}$ as determined in (9) and (13), we obtain
\[
\tau(\chi_{A_{\tau^*}}) = \sum_{J \subseteq \{1, \ldots, n\} \atop |J| = m} c_J(\tau) \det_q(Z_J) \quad \text{with } c_J(\tau) = \prod_{j \in J} c_j
\]
and
\[
\tau(\chi_{A_\tau}) = \sum_{|m| = \ell} c_m(\tau) G(m) \quad \text{with } c_m(\tau) = \prod_i c_i^{m_i}.
\]
The particular choice
\[
\tau = (q^{n-1}, q^{n-3}, \ldots, q^{1-n})
\]
leads to the following version of quantum MacMahon Master theorem:
\[
\widetilde{\text{Bos}}(Z) \cdot \widetilde{\text{Ferm}}(Z) = 1,
\]
where
\[
\widetilde{\text{Bos}}(Z) := \sum_{\ell \geq 0} \sum_{m : |m| = \ell} q^{\ell(n+1)-2 \sum i m_i} G(m) t^\ell
\]
and
\[
\widetilde{\text{Ferm}}(Z) := \sum_{m \geq 0} \sum_{J = (j_1, \ldots, j_m)} (-1)^m q^{m(n+1)-2(j_1+j_2+\ldots+j_m)} \det_q(Z_J) t^m.
\]

Remark. Let $H := \mathfrak{gl}(A)$ be the coordinate ring on the quantum general linear group (cf. [7, 8.5]). Then $H$ is a Hopf algebra which is in fact coquasitriangular or cobraided (cf. [5, VIII.5]). Thus for any finite dimensional comodule $X$, there exists a canonical isomorphism $X \to X^{**}$ of $H$-comodules, given in terms of the braiding. This isomorphism is in general not compatible with the tensor product. We note that the category of $H$-comodules also possesses a ribbon [5, XIV.6]. By composing the above canonical isomorphism with the ribbon, one obtains a functorial isomorphism $\tau_X : X \to X^{**}$ which is compatible with the tensor product in the sense that
\[
\tau_X \otimes_Y = \tau_X \otimes \tau_Y.
\]
Using $\tau_X$ we can defined a new type of cocharacter of $X$, called quantum cocharacter, as follows (cf. [4]). $\chi_{q,X}$ is the image of $1 \in \mathbb{k}$ under the map

$$\mathbb{k} \rightarrow X^* \otimes X \xrightarrow{\text{Id} \otimes \tau_X} X^* \otimes X^{**} \rightarrow H \otimes X^* \otimes X^{**} \xrightarrow{ev} H$$

where $\text{db}$ is the “dual base” map $1 \mapsto \sum_i x_i^* \otimes x_i$. As for the ordinary cocharacter, one can show that the quantum cocharacter is multiplicative with respect to the tensor product and additive with respect to exact sequences. Applying the quantum cocharacter to the Koszul complex in 2.4 we obtain an identity analogous to (8) for $\chi_{q,A_1}$ and $\chi_{q,A_1^m}$.

Explicit computation shows that, for $X = V = A_1$, $\tau_V = \text{diag}(q^{n-1}, q^{n-3}, \ldots, q^{1-n})$. Further, one can check that

$$\chi_{q,A_1} = \tau(\chi_{A_1}); \quad \chi_{q,A_1^m} = \tau(\chi_{A_1^m})$$

This explains the origin of the choice of $\tau$ in (17).
